The great density of quicksilver vapor, which cuts down the space demanded for condensation, and the small amount of heat stored up by the vapor would seem to make the problem of condensation a relatively easy one, except for the fact that a small amount of the vapor remains in the products of combustion even after they are cooled down, not only below the liquifying point, but even to ordinary outside temperatures. For this reason we find mercury still present in the gases that have passed through many hundred feet of flues and have lost their initial heat almost totally. From this it will be seen that the complete recovery of the metal is practically impossible, and the aim in constructing a plant for this purpose is to save it without undue outlay for extensive collecting apparatus. By extending the flues and chambers and by applying water to their exteriors, so as to reduce the temperature, the recovery is made more and more perfect, but it is not practicable to preserve the final traces by any means now practised.

Ores. It was remarked above that mercury comes from the distillation of a single mineral, cinnabar, the sulphide. This is practically correct, although other mineral substances contain mercury, and from one or two of them it has been won in small quantities. As a general rule these secondary substances are of small economic interest, existing for the most part as cabinet specimens. Some native quicksilver is found, especially in the outcrops of mines, and shares the same treatment as cinnabar, from which it was derived by surface oxidation. The mercurial tetrahedrite, previously mentioned, exists in some few localities and has yielded a small amount of metal. Mercurial zinc-blende may be cited as of economic value, and occasional occurrences of mercury-bearing galena have been noted. One or two comparatively rare compounds of mercury with selenium are known to mineralogists, and there are such varieties of cinnabar as the hepatic kind, which occurs at Idria, Austria, and is said to furnish a considerable part of the output of that district. Meta-cinnabarite is the black amorphous variety of cinnabar, having the same composition, but requiring

no variation in the method of treatment. Native amalgam is rare; it is a compound of silver with mercury. Altogether we are justified in repeating that cinnabar is practically the sole source of quicksilver.

Cinnabar is distinguished among metallic sulphides by its high specific gravity (8.9 according to Dana) and by its volatilizing without chemical change at comparatively low temperatures, whereas the sulphides of the commoner metals such as lead, copper, zinc, require so high a temperature for their volatilization that that operation cannot be adopted in their metallurgy. Cinnabar is decomposable in either of two ways: by heating with some strong base, as lime or iron oxide, by which the sulphur is taken up, or by heating in air, by which the sulphur is oxidized to the form of di-oxide, while the mercury, not attacked by the air, is left in the metallic state. By either method the sulphur is removed and the 'quick' left in the elemental form; or, if the heat be sufficient, it becomes volatilized and may be condensed by itself. Both methods are employed in metallurgy, the air process predominating as being cheaper and lending itself to larger operations.

Assaying. The assay of mercurial ores and products is performed in a variety of ways, all of them simple and easy. Some operators make use of iron retorts, usually quite small, holding from 1 to 10 pounds of the ore, and provided with a long exit-tube cooled by water and dipping into a small receiver. The ore is mixed with lime, and is subjected to a red heat, by which the mineral is decomposed and the metal volatilized, to be collected in the water. This method is precisely that adopted for reduction in iron pipes or retorts as worked on a commercial scale. It is satisfactory, and is employed regularly by most companies that wish to keep track of their mining and reduction, but it is not so accurate as the more minute and probably better conducted operations of the skilled assayer, who works with smaller quantities but with more care and better facilities. The preferred method is known as the gold-plate method; it depends upon the fact that when gold is placed in an atmosphere of vaporized mercury it instantly becomes amalgamated, gaining weight in proportion to the amount of quicksilver absorbed. A small amount of the ore, usually one gram, is placed in an iron or clay cup, mixed with the proper quantity of lime or other base; a small plate or sheet of gold foil is laid upon the top of the vessel, making a tight fit, and a small capsule containing water is placed upon the sheet of gold. Heated to redness, the charge gives off mercurial vapor that immediately attaches itself to the under surface of the sheet. By weighing the sheet before and after the operation the amount of quicksilver contained in the ore may be determined. By heating the plate in the Bunsen flame the mercury may be driven off, leaving the sheet in condition for another assay. Nothing can be neater than this operation. Silver may be used instead of gold, and is said to answer quite as well. In good hands this assay will detect and weigh quantities as small as one pound of mercury per ton of ore. A favorite assay with some operators is performed in a glass tube, the charge being identical with that described. One end of the tube, which is 8 inches long by $\frac{3}{8}$ inch diameter, is closed. The charge is placed in this end and the tube heated to redness, when the mercury is condensed in the cooler part. By breaking the tube and washing the condensed metal out with a jet of water it may be got into a porcelain capsule, collected into a globule by rubbing, dried with blotting paper, put upon the scale pan, and weighed. This also is accurate, yielding results comparable with the process just described. It is found that litharge, a strongly oxidizing substance, is more suitable than lime for the assay. Wet methods of analysis are far too laborious and complicated for use in the quicksilver industry and are rarely employed in America. By such means an absolutely pure specimen of cinnabar would be found to contain 86.2% of mercury, together with 13.8% of sulphur; but cinnabar, like all other economic minerals, is never quite pure, the usual content in metal running from 70 to 85%. In the assay, should the flux be left out of the charge, the cinnabar will volatilize unchanged in the absence of air and be deposited as a black sublimate, which turns red when rubbed. This is the so-called vermilion, much esteemed as a paint. This substance is produced also when the draft of the quicksilver furnace is suddenly turned off, while working in the large way.

Concentration. Several schemes for the wet concentration of cinnabar have been built upon the difference of the specific gravities of the mineral and those with which it is so commonly associated. Its specific gravity is 8.9, while that of chalcedony, calcite, serpentine, and almost all of the associated minerals, is less than 3, whence there is ample room for the application of familiar processes. The concentration does not appear to be especially difficult, but as the proportion of valuable mineral to waste is small it has been assumed by many that a close saving cannot be made, in spite of the fact that several such attempts have met with success. Cinnabar may be quite friable and soft, a mere stain upon the rock, or in solid masses of large size. Furthermore, the concentrate may be contaminated with pyrite. As this concentrate is inevitably fine-grained, its reduction must be continued in apparatus adapted thereto, whence the operation is debarred from the use of furnaces of the type that deal only with coarse material. It is found, as a general thing, that the costs and losses incurred in the combined processes of concentration and retorting exceed those incurred when the crude ore, no matter how low-grade, is treated in furnaces of the usual type, which work at extremely small cost per ton and volatilize the quicksilver almost completely. Very good furnace work is done at a cost as small as 50 cents per ton of crude ore, nor is the expense of handling crushed material in the so-called fine-ore furnaces appreciably greater. Now, as water concentration cannot be expected to save nearly as high a proportion of the metal as does the furnace, it would not appear that there is much opportunity for the profitable practice of wet methods.

Furnaces. The ancients were acquainted with mercury, but not, apparently, with the use of it. We read in the classics of cinnabar, and of the means by which it

was made to yield the metal, and we may surmise that quicksilver was first found native, but that during later centuries its extraction from the ores developed into an art, insignificant, of course, but following the lines, no doubt, along which we now work. It seems likely that the first efforts took the form, practised in later centuries, of pile roasting, so much followed in copper metallurgy, but now becoming obsolete. The pile or heap roasting of mercurial ores, though necessarily a crude and wasteful process, is not a difficult one, and requires little apparatus of any kind. In it the metal is both volatilized and then condensed in the same body of ore, the latter in the cooler parts near the surface. In carrying this out a layer of firewood is placed on the ground, upon which the ore, broken to the proper size, is placed, and the whole covered with fine stuff to control the rate of burning. The fuel being set on fire, continues to burn slowly, the heat rising gradually for some days, according to the size of the heap. The mercurial compounds being broken up by the action of air and heat, the mercury is volatilized, a portion escaping into the atmosphere, while another part condenses into liquid in the surrounding interstices of the pile. The heap is then suffered to cool, and the remains taken to be washed in tubs or sluices, the mercury being obtained in a state of purity. Out of this process, so primitive and wasteful, must have grown the present methods, which, so far as their chemistry is concerned, are identical with what I have described. The improvements consist in two principal things, the avoidance of the highly deleterious fume, and the transference of the condensation feature to fixed apparatus outside the heap. These alterations involve the enclosing of the roasting mass within walls impervious to the air and gases—in short, the provision of a furnace. We can easily imagine the earlier steps in the evolution of a modern quicksilver works, and for the later ones we have the evidence of writings composed within the last century, although these are for the most part mere repetitions, one author copying more or less faithfully what preceding ones had said. From these we gather that the course of invention has taken two directions, first toward the use of the cupola form of furnace for the reduction of coarse ore, second to the use of closed receptacles (retorts, muffles) for the treatment of finer material. The cupola has undergone many modifications, and the figures in textbooks betray a good many fanciful forms, arising from the whim of the inventor, or from local conditions. Two divisions of cupola practice are to be noted: first, the discontinuous method, in which the charges are introduced into the furnace, then heated, cooled, and discharged; second, where the process goes on continuously, fresh ore being introduced at the top while an equivalent quantity is withdrawn, spent, from below. The latter method has supplanted the former almost entirely. The commonest example of the discontinuous cupola is the Bustamente furnace, which consists of a vertical shaft, 25 ft. high by 6 ft. diameter, with a fire-place at the bottom, and provided with arches of brickwork above, on which rests the ore. This may consist largely of fine material, but in it there must be enough of comparatively large fragments to afford interstices large enough to admit the passage of the flames from below. The use of these arches is a not uncommon expedient in such furnaces, since the slight draught, always what is called 'natural' draught in contra-distinction to that made by mechanical blowers, is insufficient to propel the gases through a body of fine ore, so that the process is checked. The expedient of applying blowing apparatus has made much headway of late years, and the best works are usually thus equipped, although the blast is light in comparison with that employed for copper, lead, and, above all, iron smelting. Among the numerous disadvantages of this type of cupola are the necessity for allowing the charge to cool before it can be discharged; the amount of labor necessary both for charging and discharging; and the time required for an operation, namely, a week, the quantity of ore treated reaching 50 tons. Another arrangement, once popular, consisted of a prismatic cupola, 20 ft. high by 4 ft. wide and 15 ft. long, which contained the charge of ore, held firmly between stout brick walls. A fire-place of the same height and length, but of only half the width, was built against one side, while a condensing-chamber of a size equal or greater stood against the other. Small holes in the brickwork allowed the flames to pass through the ore sidewise, while corresponding holes in the other wall led the fume, of which the volatilized mercury formed a part, into the condenser. The furnace-compartment being filled with suitably placed ore, the fire was lighted and the whole mass of ore and brickwork raised to a red heat and kept so until the process was adjudged complete. The structure and its contents were then allowed to cool and the spent ore removed. This method is open to the same objections as the other, and all contrivances of the sort have given way to continuously-acting furnaces, usually of the round cupola type, without interior shelves, except those for the treatment of fine ore, for which the internal shelves have been retained, but far more advantageously arranged. It has been found best to give up the idea of treating fine or mixed ores in the cupola shaft, and to make a decided division of processes, using the plain cupola for the coarser fragments and the shelf-furnace for finer stuff. In general practice those fragments that are above, say, two inches in diameter, are considered fine; while stuff larger than that is denominated coarse. It is true that some fine ore can be handled in the cupola, but only by admixture with enough of the coarser kind to prevent packing down and impeding the draught. Where there is too great a proportion of fine, as happens in many mines, especially where the ore-matrix is friable, it is considered good practice to crush the whole output and treat it in shelf-furnaces, of which several excellent forms have been invented and used in California and elsewhere. By the expedient of making the shelves sloping instead of horizontal, a continuous downward feed of the ore is assured, saving much hand-work, and rendering the process of roasting extremely economical and regular. With these improvements, in which the metallurgists of California have led the way, the roasting of fine mercurial ores has become almost as easy and cheap as the treat-

ment of coarse material. There is an alternative in that we can briquette the fine material, thus converting it virtually into coarse, in which case the upright cupola may be used exclusively. The preparation of briquettes, however, involves considerable expense, estimated generally at a dollar per ton, since a binding material, usually clay or clayey ore, must be employed, say, to the extent of one-tenth the weight of the ore, added to which considerable labor is required. When properly prepared the briquettes will withstand the abrasion of handling and that caused by the impact and descent of the materials in the shaft.

Metallurgical Considerations. As in the manufacture of lime, the cupolas may be heated either by an outside fire, the flames from which enter the furnace from the side, or by feeding the fuel with the ore, both burning in their descent. This matter is governed by the character of the fuel to be employed. When charcoal or coke can be had at reasonable cost, it is fed with the ore, but when wood or bituminous coal is to be used, the structure must be fitted with fire-places in which the fuel can be burned before the smoke and flames are allowed to pass into the charge. This is on account of the soot produced so copiously by the natural fuels, wood and coal, and which, as we shall see, tend to prevent the sublimed quicksilver from coalescing in the condensers. Charcoal and coke give off but little soot, tending to become burned wholly into the oxides of carbon, devoid of anything that would interfere with the aggregation of the mercury. This is an important feature. The ordinary plain cupola is operated with less fuel than any other type of quicksilver furnace, especially when internally fired. In this case little heat is lost by radiation, nor is there any mass of brickwork to be heated and kept hot. The minimum percentage of charcoal or coke consumed by it is stated to have been 5% of charcoal, by weight; while with outside-fired cupolas 12% of dried wood has been found sufficient. At this rate a cord of dry hardwood should calcine 13 tons of ordinary ore. Much, however, depends upon the composition of the ores, those containing a high proportion of volatile constituents requiring the most fuel. Water especially takes up a great deal of heat while being converted into steam, and the decomposition of calcite and dolomite is also wasteful. These carbonates are readily decomposable at the temperature of the quicksilver furnace (say 1500°F.) and a good deal of quicklime is found in residues. About 300 units of heat is required for the expulsion of the carbon dioxide from a pound of calcite, which would require the complete combustion of one-twentieth as much carbon, or say one-tenth as much dry wood. Water requires also a large amount of heat for its expulsion, including that absorbed, first by raising it from the ordinary temperature to the boiling-point, with that which becomes latent in the steam, and that taken up in raising the steam to the temperature of the upper part of the charge, which should not fall below the boiling-point of mercury, lest a part, at least, of that metal be condensed within the fresh charge, or, still worse, within the surrounding brickwork. The sum of these requirements on the part of water is no less than 1330 heat units, equaling the amount of heat which would be set free by the complete combustion of carbon to the extent of nearly 9% of the weight of water contained in the ore.

The principal losses of heat from the cupola may be grouped under the following heads: First, through the decomposition of components of the charge; second, by radiation from the structure; third, by the sensible heat of the escaping gases and vapors; and finally the losses from the heat contained in the spent ore withdrawn from the bottom. It is impossible to estimate the extent of these losses in any known case, owing to the lack of reliable data. The first source of loss might be estimated, were the composition of the charge accurately known; but it is one of the chief drawbacks to a proper study of the whole subject that such data have never been published, and probably never compiled. The late Professor Christy thought that one-quarter of the weight of certain charges treated at New Almaden went off in the form of gases and vapors, and as two-fifths of the escaping matter consisted of steam, the average might have had a specific heat of about 0.35, whence we can compute that the total loss of heat from this source, the assumption being that their sensible heat reached 600°F., amounted to 94,500 heat-units per ton of charge. It would be even easier to calculate the loss occurring through the discharge of the spent ore, provided we knew its weight and temperature. Again, assuming the factors 0.22 for specific heat, and 300°F. for temperature, we find the loss of heat, due to the 1500 lb. remaining from each ton fed, to be 79,200 heat-units. It is, of course, impossible to estimate the loss by furnace radiation, a thing that depends upon too many factors to admit of computation; but I may state that in the smelting of copper in brick cupolas there is reason to believe that 6 or 7% of the heat generated internally, or supplied by the heated blast, is lost through the walls.

The presence of pyrite in quicksilver ores is not wholly detrimental, since it supplies a portion of the heat for distillation. Other sulphide minerals partake of this quality, though in a less degree. In places mercurial ores contain enough pyrite to enable the distillation process to proceed without the addition of any coal or other fuel, and whenever pyrite is present at all, it serves to contribute at least a portion of the heat. The sulphur is burned to di-oxide chiefly, a smaller portion perhaps to tri-oxide, which develops itself into sulphuric acid in contact with water. The iron would, in all probability, be converted into the magnetic oxide. Pyrite, when burned to sulphur di-oxide and to ferric oxide, has a calorific power one-third as great as that of coal, pound for pound. Such being the case, it would seem that a charge containing as much as 15% of pyrite should roast without the use of other fuel. Of all the forms of quicksilver furnaces, the simple cupola is the most economical of fuel, notwithstanding the loss of heat; it is especially more economical than those constructions known as discontinuous furnaces, of which the retort-furnace is the most wasteful of fuel.

In the retort-furnace the flames from the fire-place do

not come in direct contact with the ore, but heat it by conduction through the walls of a receptacle (retort) in which it is placed. It follows from this that the gases of combustion do not intermix with those driven from the ore, a fact having an important bearing upon the condensation of the quicksilver in the latter. Heating in this way is wasteful of fuel, and only permits of small quantities being acted upon at once; whence the capacity of such furnace is very limited. The retorts in common use do not hold more than two or three hundred pounds of ore at the most, nor can the work be hurried, since the transfer of heat through the walls is slow. All ores being bad conductors of heat, it has been found inexpedient to make the retorts of a greater diameter than 15 to 20 inches, and they are generally smaller, their small size adding greatly to the cost of charging and discharging. They are only adapted to comparatively fine and rich material, since the expense of working is too great to permit the treatment of low-grade ore. Retorts are ordinarily made of cast-iron and are of cylindrical or semi-cylindrical form, the latter closely resembling the vessels used in the preparation of illuminating gas from coal. A number of retorts, usually two to ten, arranged in parallel are set in or over a single fire-place, the structure being termed a 'bank' or 'bench.' An operation that includes charging the vessels, heating, and discharging them, consumes fully 10 hours; so that even the largest plants of this kind can scarcely treat more than two or three tons in a day of 24 hours, and at an expenditure of labor and fuel incomparably greater than when cupolas are employed. The extraction of mercury is less perfect than in cupolas, and they are usually run only as a makeshift until better apparatus can be installed. In spite of an improvement, taking the form of an inclined muffle (Fitzgerald's furnace) which permits of continuous feed and discharge, furnaces of this general type seem doomed to extinction. Those of the reverberatory type have been used for quicksilver, especially in foreign countries, in spite of manifest disadvantages, among which the excessive consumption of fuel and the production of a great volume of smoke are the most conspicuous. The principle of the reverberatory is the heating of the charge by reflection of heat downward upon the ore in a layer beneath. The ore is fed into the end farthest from the flames and is drawn forward by hand-tools, getting progressively hotter and hotter until it arrives at a point beyond the space of maximum heat, to be discharged finally. Only comparatively fine material is adapted to this treatment, and the quantity handled is not large. A modification of the flat-bedded reverberatory—the Livermore furnace—had some vogue in this State in former years, and possessed points of interest, especially in the inclined arrangement of its bed. The inclination was such that the ore, introduced at the upper end, followed down a series of parallel grooves in the bed and was discharged by gravity at the bottom. The flames playing over the surface heated the ore to the required temperature. Since this involves less labor than the ordinary form of reverberatory it is more likely to have imitators in a country where wages are high. The fuels proper for reverberatory and retort furnaces alike are the long flaming sorts, such as wood, bituminous coal, and petroleum. In the reverberatory there is ample opportunity for the complete combustion of the fuel, without the production of soot and tar, which are unavoidably formed when wood and bituminous coal are burned in a confined space, as in a cupola.

Condensation. The smoke of quicksilver furnaces in which the products of combustion of the fuel are intermixed with those derived from the ore itself contains sundry constituents that affect the subsequent process of condensation. The principal are nitrogen, derived from the air; carbon dioxide, derived from the fuel and sometimes in part from decomposed carbonates; carbon monoxide; water-vapor, derived from both ore and fuel; tar and soot, derived from the fuel generally, but sometimes in part from hydrocarbons contained in the ore; the vapor of mercury; and solid particles (flue-dust). The mercurial vapor usually constitutes but a small part of the whole, but its condensation and preservation render necessary the cooling of the whole, whereby not only the mercury but the tar and water also are condensed, adding much to the cost and complexity of the process, the incidental condensation of the sulphur gases increasing the difficulty.

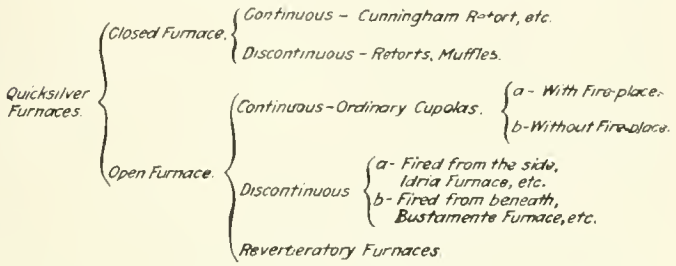
When mercury is stirred with such materials as grease, sugar, sulphur, oil, etc., the liquid metal is converted into a gray powder, called 'floured' mercury or 'deadened' mercury. It may be brought again into the liquid form by rubbing. The mercury exists in this powder in globules said to measure only one twelve-thousandth of an inch. The same effect is produced by the soot given off in burning the fuel in a furnace; this accompanies the mercury into the condensers, flours it, and renders it more difficult to save. The mercurial soot in such a case is treated in a variety of ways, as by working with a tool, mixing with ash, or lime, and by pressing; after which the remaining sooty mixture, still containing some mercury, is sent back to the furnace to be re-sublimed. The treatment of mercurial soot is an important part of the technique of quicksilver reduction.

Some means of condensing the quicksilver vapor has to be employed in connection with every quicksilver furnace, whatever its type. Various means of getting the mercury into the liquid form are practised, all based upon the abstraction of heat from the fume (smoke, gas, vapor) whereby some of the various constituents are brought below their dew-points and settle in drops. Among those that condense is mercury itself, which is very easily brought down; so easily, in fact, that it begins to condense within the furnace, at points that do not reach a temperature above the boiling-point of the metal. But since the vapor of mercury on cooling forms small globules—a mist—which to some extent remain suspended in the air, and since also a portion remains quite uncondensed in air at all temperatures, the problem of condensation becomes intricate. Furthermore, other smoke constituents become condensed at the same time, intermingling with the mercury and adding to the cost of its recovery. It is apparent that the whole volume of

smoke requires cooling, so that the problem becomes one of no small moment in the case of all furnaces and especially open ones, where the products of combustion are allowed to mingle with the mercurial vapors. The apparatus of cooling is diverse in character, but all systems are capable of being classified either into (1) cooling by atmospheric air; (2) cooling by water; or (3) cooling by means of ore. The last has been used in a limited way, and consists merely in placing the cold ore in a layer on the iron top of the hottest condensing chamber, whereby it becomes dried and warmed, while at the same time the temperature of the chamber beneath is reduced in like degree. Or, boxes for the temporary reception of the ore are sunk within the chamber, producing the same result. This method is scientific in that the heat abstracted from the smoke is returned to the furnace. It would not be practicable to carry it so far as to cool the smoke of open furnaces to the condensing point, as will be seen.

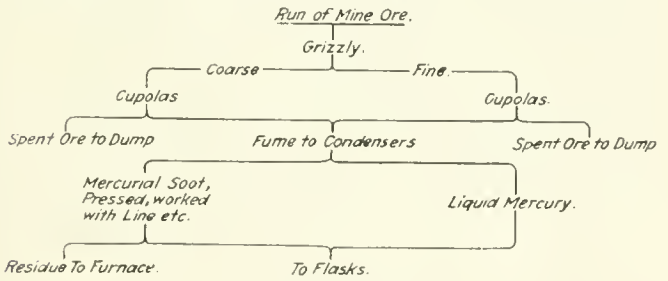
Cooling by atmospheric air involves the conduction of the heat of the escaping gases and condensing matters through the walls of the flue or its enlargements (chambers) and its dissipation in the surrounding air. This would not be difficult were it practicable to employ materials of good heat-conducting powers for the construction. Sheet-iron would be the obvious choice, but owing to the character of the smoke, it is impracticable to employ iron or indeed any other metal. All mercurial ores contain at least a little sulphur, namely, that combined with the quicksilver, and most of them contain a larger quantity held in the pyritic minerals, all of which give it off in the furnace, forming, as before said, the di-oxide and tri-oxide of sulphur, the latter of which, on meeting water-vapor unites therewith, forming sulphuric acid, which is most corrosive, acting readily upon wrought-iron and steel, and more slowly on cast-iron. As these effects are accentuated by the presence of moisture, an ever-present concomitant, it cannot be expected that chambers composed wholly or partly of rolled metal in sheets or plates will endure; and experience shows them to be practically worthless. However, cast-iron, which may be had in thick plates, has found some use in the bottom of such chambers, for which it is well fitted, owing to the ease with which mercury-tight floors may be made. In such places plates two inches thick and upward have been found to last for two years or more, even when the acid solutions settled directly upon them. When kept dry, as happens when the temperature is so high as to preclude the condensation of the vapors on their surfaces, even wrought-iron and steel sheets are unaffected, as is also shown in the good preservation of boiler-tubes heated by the exhaust-gases of copper and other furnaces that contain oxides of sulphur. These facts suggest some modifications of the present construction of mercury condensers.

Lead, while unaffected or but slightly affected by the sulphur gases, is quickly amalgamated by the mercury itself; hence is inapplicable. Either from one cause or another, and from their too great cost, all other metals have been found inapplicable, and the main reliance has been masonry work for the condensing apparatus, supplemented by earthenware tubes, and in California the use of wooden or wood and glass constructions, of which the best examples are found at New Almaden. Masonry and brickwork are objectionable in that they are poor conductors of heat; the gases, after passing through successive chambers of great size, still remaining hot, and requiring further cooling by means of long



CLASSIFICATION OF FURNACES.

flues, tubes, etc., before being discharged into the atmosphere. It often happens that the first chamber is so hot as to collect no quicksilver at all. Again, they tend to absorb the metal in the interstices, and furnaces have been run for days and weeks before the pores were so filled as to allow any mercury to appear on the floor, where it should be found. Nevertheless, they are the mainstay of the process as generally conducted. Wooden constructions possess the merits of being cheap and of being resistant to acids. Thin boards are used, which, although poor conductors of heat, lend themselves to



A FLOW-SHEET.

fairly efficient uses. When combined with glass they are unsurpassed in efficiency. The glass is ordinary window-glass, set in panes in the wooden framework. It is superior to any other material, since the internal heat is not only conducted but is radiated from the interior outward. Experiments have shown that 80% of the heat rays striking normally on glass panes pass through. Chambers of this kind, therefore, cool the gases far more readily than any other construction that depends upon atmospheric cooling.

In retort-furnaces, where, as before said, the mercurial vapors are unmixed with combustion gases and are therefore far less bulky, they are condensed by simple means. It is only necessary to provide a fairly long pipe, which may be cooled by the flow of water. At times even this water-cooling is discarded and the pipe so arranged as to dip slightly into water at its extremity, the condensed mercury flowing down the tube and collecting in a trough just below.

The use of water in this way to cool the mercurial fume has been practised in many localities, as supplementary to air-cooling. In some cases water-boxes of cast iron have been built into the roofs and walls of the condensing chambers, while in others sprays have been used, playing upon iron surfaces, particularly the roofs, with great effect. It is rarely, however, that the water has been introduced directly into the stream of gas, where it would be most effective, chiefly, no doubt, because of the soot and minute globules of metal that it would be supposed to carry off. There is no question, however, that with suitable means for filtering the liquid, this source of loss could be obviated, when builders would be free to utilize water-cooling to its full extent. Water-cooling has undeniable advantages over air-cooling, especially in the lessened extent of surface necessary, and the consequently cheaper and smaller constructions. It would seem possible in this way to reduce the cost and size of the condensing arrangements, probably to one-fourth of that now considered necessary, and at the same time reduce to almost nothing the absorption of mercurial metal into the walls. This would involve the use of a liberal amount of water, with provision for its filtration to remove suspended matter, the cooling of it, and its return to the chambers. The liquid would no doubt become contaminated with sulphur oxides, which, after a time, would render it acid and compel disuse; but it would be feasible to neutralize the acid, by means of limestone, or in some cases by the burned lime or dolomite so often found in the spent ore. Considering the great capacity for heat that water has, there should be no difficulty in devising apparatus to carry out this purpose in far less space than is now considered essential.

Perhaps the most rational way to employ air-cooling consists in passing air through a series of tubes contained in the hottest part of the first chamber, and then leading it to the furnace, by which a supply of preheated air is obtained to aid combustion, and at the same time the smoke is cooled to some extent. Tubes containing water act still more effectively, and it would seem practicable to heat the boiler feed-water in tubes so placed, thereby intercepting heat that would otherwise be lost, and so conserving fuel that would otherwise have to be burned to produce power. We can proceed thus far with economy and actual benefit to the process. Beyond this the heat abstracted from the gases would have to be wasted, for whether it be taken up by the outside air or by the cooling water it would ultimately be for the sole purpose of cooling the smoke, and would then be bestowed upon the surrounding atmosphere, as indicated.

Strong inducements exist for the wholesale application of water to cool and condense the gases of quicksilver furnaces, the chief of which lies in the possibility, even the ease, of condensing the mercury in apparatus occupying small space as compared with that in common use. Such apparatus would not differ in form from that used in a variety of arts, where it is necessary to purify the smoke of other metallurgical works, particularly where sulphur fume is evolved. Towers filled with coke, quartz, or acid-resisting bricks or tiles are common in such industries, and their capabilities are well understood. The spraying of fume much more corrosive than that evolved from mercurial ore is done successfully, and even the application of caustic lime, zinc oxide, and other absorbents for neutralizing deleterious gases is becoming common. With all this wealth of invention and experience at the disposal of the quicksilver metallurgist, it would seem strange if the cumbersome methods of the past do not soon become in a manner obsolete. In this connection I may remark that metallurgists will do well to ponder the advantages of such new inventions as Cottrell's device for precipitating certain constituents of smelter smoke, such as fine solid particles, sulphur tri-oxide, etc., with much success. Apparently this invention should succeed admirably when applied to quicksilver condensation. Evidently it would take the place of constructions that involve the principle of sedimentation, found important in this art. This implies the use of extended surfaces of contact, the object of which is to throw the mercurial globules by the influence of contact alone.

Diseases Caused by Mercury. The important matter of the effects of mercury upon the animal system, and especially upon the health of humans, demands strict attention. The breathing of mercurial fumes, and even the prolonged contact of those ores and compounds with the human body, whereby small amounts are absorbed into the system, produces consequences so grave that the utmost care must be observed both by the workmen and those in charge of the operations to lessen the danger of contamination. Mercury acts prejudicially upon the nervous system, it impairs the digestion, it injures the motor functions, it impoverishes the blood, and produces, or at least predisposes to, scurvy and scrofula. These and other ill effects are so common among workers that for a long time they were supposed to be unavoidable and were taken as a matter of course; and it is only of late years that, the cause having become understood, they have been prevented. Perfect cleanliness is enjoined as the best preventive, but such additional safeguards as acid foods and avoidance of alcoholic drinks are also insisted upon. Since it is supposed that the mercury taken into the system exists there in the soluble form, it has been suggested that the use as medicine of such chemicals as would naturally tend to render it insoluble would be indicated; and for this purpose potassium iodide is recommended. Other physico-chemists have maintained that the potassium chlorate might act as beneficially. Probably the most effective means of preventing mercurial disease consists in adding suction apparatus to the plant, by which the draught is inward at all points throughout the chain of furnaces, condensers, and flues, thus preventing the escape of vapors until the exit-chimney is reached. A further great improvement tending to the same happy result consists in so designing the works that the handling of the spent, but frequently hot and smoking, ore shall be reduced to a minimum. Little attention has been bestowed upon this feature, and in works now running we see men engaged in raking the dangerous stuff from the furnaces.

Soap as a Frothing Agent in Flotation

By M. H. Thronberry

MANY attempts have been made to use soap as a frothing agent in flotation. These attempts have been on the whole unsuccessful; and oil has come to be considered pre-eminent among substances that can produce frothing. At the present time the price of frothing-oil is increasing; and, in consequence, some of us decided to see if soap could not successfully replace oil as a frothing agent.

In solving this problem I am indebted to H. T. Mann, Associate Professor of Metallurgy in charge of the department in the Missouri School of Mines, for his many helpful suggestions. Carl Stifel, a student in the same institution, also helped by doing a great deal of the preliminary work.

In order to be able to calculate the exact quantity of the frothing agent used in each charge, a solution was made by dissolving five grams of a given soap in water and adding water until the final volume of the solution was 500 cc. The ore used was galena in a dolomite gangue, assaying 5.03% lead. A screen analysis of the ore gave the following results:

Mesh	Average size Mm.	%	Lead %
On 65	0.251	0.75	10.03
" 100	0.177	7.50	7.96
" 150	0.125	18.25	4.93
" 200	0.091	20.75	3.55
Through 200	....	52.75	4.87

Before running any charges in a machine, a series of preliminary tests was made of all the oils in stock in order to classify them as 'frothing' and 'non-frothing.' After this classification was made, a number of experiments were performed with the selective oil that was best suited for this ore as a collector of the lead and that at the same time did not interfere with the frothing agent.

A Minerals Separation machine built in the School shops, after the model described in the *Engineering & Mining Journal* of September 4, 1915, was used in this work. The machine differed from the model in the following particulars: The agitation-box was made three inches higher to prevent splashing. The impeller has two agitators, one placed about two inches above the other. A glass plate two inches wide by six inches long was placed in each side of the spitzkasten for the purpose of judging the height and nature of the froth.

The charge for each experiment consisted of 800 grams of the ore in 3200 cc. of deep-well water. This water carries a large percentage of lime and magnesia. After the charge of ore and water was put into the machine, it was agitated for a few minutes, then 0.5 cc. of oil from crude water-gas tar was added, and the agitation continued for five minutes, after which just enough soap solution was added to form a good froth. The froth that formed during the first 30 minutes was removed and called the 'concentrate.' The charge was then re-oiled and, if necessary, more soap solution was added. During the remainder of the run the froth collected was called a 'middling' product. The results of these tests are shown in the following table:

TABLE I

ORE. Dolomite and galena; assay = 5.03% Pb.

OIL. Kind, oil from crude water-gas tar; amount used, 0.9 cc.; pounds per ton, 2¼.

OPERATING DATA. Time = 45 minutes; amount of water = 3200 cc.; amount of ore = 800 grams; speed of machine = 1700 r.p.m.

	Soap			Concentrate		Middling		Tailing		Extraction	
Test No.	Lab. No.	Am't. Cc.	Oz. Av. per ton	Weight Lb.	Lead %	Weight Lb.	Lead %	Weight Lb.	Lead %	Apparent %	Actual %

TABLE II

Ore. Same as Table I.
Operating Data. Same as Table I.
Oil. Kind, oil from crude water-gas tar; amount, 0.9 cc.; pounds per ton, 21.

Test No.	Soap Lab. No.	Soap Am't. Cc.	Soap Oz. Av. per ton	Concentrate Weight Lb.	Concentrate Lead %	Middling Weight Lb.	Middling Lead %	Washing Weight Lb.	Washing Lead %	Tailing Weight Lb.	Tailing Lead %	Extraction Apparent %	Extraction Actual %
1	1	10	1.0	17.60	78.2	19.5	57.6	31	12.32	715	0.61	88	62
2	3	3	1.2	18.65	79.3	23.5	52.0	37	11.50	697	Trace	99	68
3	10	3	1.2	14.35	80.5	15.7	71.0	28	17.50	731	0.72	86	57
4	14	3	1.2	23.00	82.7	16.1	72.2	32	12.70	616	0.32	89	76

The apparent extraction was calculated as follows:

H = percentage of lead in heading.
C = percentage of lead in concentrate.
T = percentage of lead in tailing.

$\frac{C(H-T)}{H(C-T)}$ = Apparent extraction.

The actual extraction was calculated by finding the grams of metallic lead in the concentrates and middlings; adding these results and finding what proportion this was of the metallic lead in the feed.

The recovery in all cases is lower than it should be, owing to the fact that the machine is constructed of wood, so that oiled sulphides cling to the sides. When the tailing is withdrawn and the machine washed out these sulphides go into the tailing, thereby increasing the percentage of lead in this product. Table II shows to what extent this factor influences the final results.

A composite sample of the tailings from runs No. 1 to 18 was taken and a screen analysis made of this product to determine where the losses were, as follows:

Mesh	Average size Mm.	%	Lead %
On 65	0.251	1.04	10.20
" 100	0.177	7.40	6.00
" 150	0.125	14.32	2.68
" 200	0.091	18.32	1.54
Through 200	....	58.92	1.18

Comparing this analysis with that of the original ore, it is very evident that practically none of the material on plus 100-mesh floated. Hence, the conclusion is that the concentrates were made up of minus 100-mesh material, and that this high tailing is due to the coarse lead remaining.

In order to check the above statement, a portion of the ore was re-ground and passed through a 150-mesh screen of 0.104 mm. opening. Four tests were run on this material. The results are shown in Table III.

The following points are noticeable:

1. The amount of oil and soap required is less than for treating the coarser material.
2. The weight of the concentrate is greater but it contains more gangue.
3. Less lead was left in the tailings.
4. The percentage of recovery is higher.

A few experiments were made to determine the effect of an excess of soap. Table IV shows these results.

The following conclusions are drawn:

1. That soap can be used as a frothing agent in the flotation of galena, when used in combination with a suitable selective oil.
2. A small amount of soap must be used in a frothing agent, for when used in large quantities the gangue floats with the concentrate.
3. The lead in the tailings is due to two things:

(*a*) The oiled sulphides stick to the sides of the machine and are washed into the tailings. This would not occur in continuous operation, but is of interest in tests.

(*b*) The material floated is principally of minus 100-mesh, the coarse material going into the tailing.

Mining in Utah

By L. O. Howard

The mining industry has never been more prosperous. Regular producers are increasing shipments steadily and the smelters are operating to capacity. High metal prices have enabled many old producers to resume. The coming of spring has stimulated state-wide activity, and no one district has a monopoly of interest. With the product of the Utah Copper Co. sold months ahead, the increasing demand and price for lead ores, the long-delayed rise in silver, operators are well content. There have been some shipments of tungsten ore. A few cars of manganese ore have been shipped from Emery county, and in the Tintic district the Chief Consolidated has started production of manganese from its property in Homansville, and expects to make some large shipments in the near future. There is a slight increase, even, in the activity in the radium districts, some of the producers having sold a little ore to the Government, and a few independent buyers taking small lots at prices 25 to 33% less than before the War. Developments in potash follow one another rapidly. Two strong companies are at work at Marysvale, two others are at work on the brine of Great Salt lake, and the Pennsylvania Salt Co. is reported to be backing an enterprise looking to the extraction of aluminum from the alunite of Marysvale, but no authentic data can be obtained as to how this is proposed to be done. Ozokerite production has been begun by one plant in eastern Utah. There is even a mild interest in drilling for oil in southern Utah. The seasonal dullness in coal mining has arrived. The principal development of interest to coal operators was the final decision of the Secretary of the Interior awarding title to 4160 acres of coal land in Emery county to the Freed estate. Six years ago patent to this land was denied on the ground of fraud and indictments were secured against some prominent coal-men and mining attorneys. Final vindication of these men has been well received.

Dividends for the first quarter surpass all past records. They total $4,795,475, of which Bingham mines contributed $4,286,225, Park City, $326,250, and Tintic, $146,000. One mine in Beaver county paid $25,000, and the Lakeview distributed the balance of $30,000. It is expected that others will appear on the list soon, and the present rate will be exceeded. A record of over $20,000,000 is confidently expected for 1916.

At Park City the old producers are shipping heavily. Among the improvements in immediate prospect are the electrolytic zinc plant of the Daly Judge, increased capacity for the Broadwater mills, completion of the Daly Judge surface improvements, electric hoist and compressor, electrification of the Daly mine, and a new 50-ton mill and 2-mile aerial tramway for the Silver King Consolidated. All of these improvements are of a permanent nature and reflect the increasing prosperity of an old district. Operations have been resumed at the American Flag mine, and at the Daly West mill. Shipments in March were 6110 tons of ore and concentrate, contributed by 11 shippers.

At Bingham production is being rushed by both copper and lead mining companies. The Utah Apex is shipping 600 tons of lead ore daily. Utah Consolidated has paid a dividend of $225,000. The lease on the Ohio Copper property is treating daily 2400 tons of ore, which is said to contain a little less than 1% copper, of which about 50% is saved. There is renewed talk of a reorganization of the company.

The latest addition to the shipping list at Tintic is the Tintic Standard, which has commenced production from a large body of galena ore on its 1500-ft. level. This is tangible reward for the persistent efforts of its management in the face of discouraging and even disparaging opinion of many of the 'experts' on Tintic ore-deposition. Properties on which work has been resumed or announced are the Zuma in East Tintic, the Utah Consolidated, Carisa, and Tintic Lily, which will sink to 1000 ft. Another shift has been added at the Gold Chain and Grand Central. The territory of the Beck Tunnel and the Plutus is to be explored in the hope of restoring these properties to active production. The Eagle & Blue Bell has resumed shipments after completing the installation of a new electric hoist and compressor. The Iron Blossom has announced a dividend of $100,000 to be paid in May. The Sioux Con. has been stimulated by developments in the Iron Blossom to seek the extension of the great copper orebody in its own territory.

From Beaver county comes the announcement of new work by the Beaver Copper and the Beaver Lake Metals in the Beaver Lake district; Los Angeles capital for the Goldzone of Fortuna, the discovery of a new silver-lead orebody on the vigorous young Moscow, the commencement of development on the Nellie group, resumption of work by the Knights on the King David and Indian Queen at Frisco, rumors of resumption at the famous old Cactus. The Mammoth Copper Co. has been incorporated to operate a new property 14 miles northeast of Milford. Development has proceeded to the point where it is planned to ship four cars of copper ore per week. The Horn Silver has been enabled to pay another dividend of $25,000 from the proceeds from the bond and lease on its dump, which the Caldo company is treating by flotation.

Many more companies are planning work in Big and Little Cottonwood. Among them are the Howell, adjoining the Cardiff on the west, and now under control of Cardiff officials; the Canton, an old-timer; the Cottonwood-Atlantis, controlling the old Moltke mine near the South Heela; and the Secret. The Sells, Alta Con., and Michigan-Utah are shipping. The Cottonwood Metal has taken over the Walrous ground and will equip it. An agreement has been reached by the City and County of Salt Lake and the Maxfield and Cardiff mines providing for the expenditure of $30,000 in widening and straightening the Big Cottonwood road, in order that tractors may be substituted for horses, and one source of contamination for the city's water-supply be eliminated.

Geological Conditions at the Panama Canal

Some engineering problems of the Panama Canal in their relation to geology and topography are discussed by Donald F. McDonald in Bulletin 86 of the United States Bureau of Mines. Mr. McDonald was detailed as geologist to the Panama Canal, while it was under construction, and is now with the Bureau of Mines. The paper aims to discuss, from the viewpoint of the mining geologist, the bearing of topographic and geologic conditions on certain problems that arose in the construction of the Canal.

In all, there is a clear record of four oscillations in the region of the Canal and the beginning of another elevation. The average rate of uplift for, say, the last 1000 years has been less than 3 ft. in 100 years. It is believed that the sinking of the ocean bottom outside the relatively shallow depths of the isthmian shore-waters has been the chief cause of the earthquake periods that have, so far as the records go, visited the isthmus every 30 to 35 years and that each of these seismic disturbances has resulted in some increased elevation of the land mass. From the various oscillations of the land above and below sea-level, one would expect that the rocks constituting the isthmian land mass would have become broken and dislocated in these upward and downward movements, and this is the case. Great fracture planes cut the rock and trend mostly north-east and south-west, or approximately parallel with the axis of the land mass, with some minor fractures leading in other directions. Along these fracture planes differential movements, some of which measure hundreds of feet, have taken place. The frictional drag of these movements has crushed and broken the softer rocks for several feet on each side of the plane of motion.

This faulting has had an important bearing on engineering, because the faulted zones, especially where the rocks are extensively crushed and broken, have tended to promote slides. Culebra Cut is a vast ditch that passes through many varieties of rock in the nine miles of its length. Some of these are weak and unstable, and where the slopes of the cut were steep and from 100 to 300 ft. high, the weaker rocks were crushed down to flatter slopes. The flatness depended on the material involved, but, whatever the material, whenever the slope got flat enough the sliding stopped. The slides have made necessary the excavation of about 30,000,000 cu. yd. more than was included in the first estimates for Culebra Cut, but they have not in the past and will not in the future endanger the ultimate success of the Canal. The largest and most important slides developed from structural breaks and deformations. Fortunately, they occurred only near Culebra in a section of the cut not much over a mile long. These deformations first manifested themselves by the appearance of either one or of a set of cracks or fissures parallel or somewhat oblique to the edge of the cut, and from a few to hundreds of yards back from it and from each other. Some of them were traceable on the surface for several hundred yards and gradually developed into perpendicular crevices as much as one-third of a yard wide and many yards deep.

Though it is not impossible that a destructive earthquake might visit the Canal, still it is extremely improbable for the following reasons:

1. The large number of tremors detected every month by the recording instruments is evidence that slow adjustments are constantly taking place and thus that no great accumulations of stress that might later culminate in a big shock are probable.

2. The absence from the Isthmus region of high mountains and of geologically recent volcanic activity is evidence in favor of the probable absence of earthquakes, especially as such high mountains are a striking geologic feature of the whole Central American earthquake belt.

3. The presence of numerous small faults and of the faulted conditions of such volcanic cores as Gold hill and Contractors hill is evidence that adjustment here has progressed well on toward normal conditions of equilibrium.

4. The tensile strength of the majority of the rocks within the Canal Zone is rather low, and they would shear with comparative ease, thus preventing any relatively great accumulation of stress that might result in a comparatively intense shock. However, experience teaches that where earthquakes happen, the buildings suffering the maximum destructive effects are those built on loose and friable material. This consideration might therefore subtract a little from the saving benefits of the yielding and preventive qualities of the Canal Zone rocks.

5. Over 300 years of earthquake observation shows only two shocks of considerable magnitude, and there is every reason to believe that the severest of these would not have seriously damaged even the most delicate parts of the Canal.

That many small and harmless shocks will traverse the Canal Zone is certain but that the Canal is in any real danger from earthquakes is contrary to all the evidence.

IMPROVED CONDITIONS in the mining industry are indicated by the prosperity of the houses that manufacture and sell mining machinery, as compared with the lean year just preceding. For example, Ingersoll-Rand Co. earned $5,459,884 in 1915, as against $1,967,723 in 1914, and had a surplus on hand January 1 last of $5,333,323. Sullivan Machinery Co. had net earnings in 1915 equivalent to about 14% on the capital stock.

EFFICIENCY ENGINEERS are disturbed over a bill introduced in Congress to make it unlawful for any officer, manager, superintendent, or foreman, having charge of work for the U. S. government to make "with a stop-watch a time-study of any job of any employee of the government."

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

CORROSION is an electrolytic phenomenon.

VEINS containing tungsten minerals are as a rule found near intrusive igneous bodies, mostly granites and quartz-monzonites, from whose magmas the vein-minerals are believed to have been derived.

ISINGLASS is a term frequently used for mica. This is wrong. The former is a gelatine obtained from the sturgeon, a Russian fish; while mica is a silicate of alumina and potash, usually associated with gneiss and schists.

TO SLAKE LIME is to assuage or quench it with water, forming the anhydrous calcium oxide, called quicklime or slaked lime, not slack-lime. The process is called 'slaking,' not 'slacking.' The latter is a common corruption which should be avoided.

MINING METHODS at the Copper Queen, Arizona, were as follows in 1915: square-set, 65.9%; top-slice, 18.79%; cut-and-fill, 15.2%; and shrinkage, 0.2%. The second and third systems increased 4.8% and 7%, respectively; square-set decreased 10.2%; these changes reduced the cost of ore extraction.

CEMENT produces a peculiar skin eruption, resembling the itch. It is caused by the alkaline content of the concrete acting on the skin of the hands and face, especially where already softened by water. Cloth gloves, the covering of the skin with a fat or grease, and careful washing will prevent the inconvenience.

STORING FUEL-OIL under water for the use of submarines is accomplished by employing submersible barges in the form of a tank 150 ft. long and 30 ft. diameter with hemispherical ends. This tank will hold 2400 tons of oil, and can be submerged by admitting water to the compartments at the ends. Compressed air may be used to bring the vessel to the surface.

COSTS in the zinc-lead region of Missouri-Kansas-Oklahoma are remarkably low. At Webb City one sheet-ground operator reports from $1 to $1.25 per ton for mining and milling; another in similar ground at South Carterville, $1.40, 35c. being treatment charge; and in the Miami district, all expenses, including insurance, etc., was $1.07 per ton over a period of 2½ years.

EMERALDS at Muzo, Colombia, are found in a formation of thin beds (⅔ in. thick) of shale and limestone alternating, the former predominating. The shale is a dense, black rock, soiling the hands with excess carbonaceous matter. The beds are gently to severely folded, in places contorted. Fractures are prominent, mostly 'healed' by calcite. The stones are seldom found in the shale or limestone alone, but usually in the calcite veins. Open-cut is the method of mining. The emerald-bearing calcite is removed by hand and sorted.

CHAINS are designated by the diameter of the rod from which the links are made, as ½-in., ¾-in., etc. Also they are distinguished by the form of the link, as close-link, in which one link is just large enough to enclose the two adjacent ones; open-link, in which the link is larger; bar-link, which consists of open links with a bar across the middle of each; twisted-link, applied usually when the twist is 90°; and straight or flat-link, when the twist is less.

THE 8-HOUR shift as introduced at a number of mines has proved successful. In most regions, white men will do as much drilling, tramming, or other hard labor requiring sustained energy, in eight hours as in ten. On the other hand in some out-of-the-way or Southern districts, where a leisurely mode of working still prevails, it would be impossible to spur the men to do as much in eight hours as in ten, and for the most part such workmen probably prefer the longer day in which they can take things more deliberately.

THE BRITTLENESS of copper, developed during the smelting and frequently ascribed to 'burning,' is in reality a de-oxidation. This brittleness in commercial copper is said to be caused by the too-great reduction of the cuprous oxide around the copper grains, leaving a spongy mass of little mechanical strength. Therefore in the process of smelting, it has been found advisable to leave a small amount of oxygen in the copper, in order that it may retain the desirable properties of ductility and strength.

POWER PRODUCTION is changing from reciprocating types of machinery to rotary types. This change has been a marked feature of the machinery field during recent years. The steam turbine is replacing the reciprocating engine for many purposes. The centrifugal pump often is substituted for the reciprocating pump; rotary condensers, rotary air-blowers and compressors are finding favor. The advantages urged for the rotary units are simplicity of design, small space, balance, low cost, and maintenance. The steam turbine, too, uses steam that otherwise would be wasted.

UNWATERING a shaft of the Catskill aqueduct in Morningside Park, New York, for the purpose of inspection or repairs, is accomplished by four-stage centrifugal pumps. The peculiar point is, however, that the pumps are floated on the surface of the water in a hollow steel cylinder partly submerged. The water enters the pumps by passages in the bottom of the float, and, as the submergence of the float is constant no matter how much the water in the shaft may be lowered, no change occurs in the pump intake. This device is not new and has been used for unwatering mines, but is simple and interesting.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

FLAT RIVER, MISSOURI

Revival in Old Districts.—Improvements at Flat River.

The Madison County district in south-eastern Missouri is the scene of great mining activity this spring. Eastern capital is interested, and several neglected properties are being re-opened. The Catherine mines are being worked after having been closed for several years. A great deal of land is being purchased by outside people for future development.

Other old mines to be re-opened are the Silver proprties on the St. Francis river, about 10 miles west of Fredericktown. These mines were operated about 40 years ago for lead and silver, and later closed. The old shafts are being cleaned out, and a hoist erected. Tungsten is searched for, and a test shipment of 1250 lb. has just been made.

In the Flat River district the Federal Lead Co. is building its new mill, day and night, and expects to complete it this summer. In its other plant the company has installed a Marathon mill for testing purposes, and is at present grinding the jig middlings for table treatment. These mills are still in the experimental stage.

The St. Joseph Lead Co. is working on plans and specifications for a new power-plant to cost $250,000, to be constructed at Rivermines this summer and fall. The building will be of steel and brick, and should be one of the best in the State. The engine will be a steam turbine of 3500 kw., single unit, and is so arranged that a duplicate can be installed later. The new plant will run in parallel with the present system. The company has a steam-turbine plant at Leadwood, and a gas power-plant at Bonne Terre.

The Desloge Lead Co. has installed a Hardinge mill, to grind the oversize of the jig middlings. The discharge is sent to a Dorr drag-classifier, the overflow going to flotation, and the drag discharge returning to the mill circuit.

LEADVILLE, COLORADO

Further Drainage Schemes.

A contract has been closed between the Western Mining Co. and the Empire Zinc Co. for lowering the water in the Wolftone shaft from its present level at 800 ft., 180 ft. to what is known as the 1000-ft. level. The draining of the Wolftone to this depth will give access to immense bodies of sulphide ores now under water, and will completely drain the Robert Emmet shaft, 850 ft. deep, which, with surrounding territory was recently purchased from the Small Hopes-Boreel Mining Co. by the Empire Zinc people for $500,000. J. H. Bowler, with W. C. Jones, of the Layne & Bowler Corporation, manufacturers of the Layne centrifugal pumps with headquarters at Los Angeles, California, is here installing the sinking-pump in the Wolftone shaft. The pump is a vertical turbine with a capacity of 2000 gal. per minute. It is being placed in the shaft at the 800-ft. level and connected with the large steam plant now operating at that point. The steam plant has a capacity of 2000 gal., and at the present time is throwing only 650 gal. per minute. The sinker will force the station equipment to its limit, and will drain the shaft at the rate of 1350 gal. per minute. The unwatering is estimated to require from two to three weeks. The selection of the Layne type of pump is largely due to the decision of the manager of the Western Mining Co., S. D. Nicholson, who made a personal inspection of the Wolftone shaft prior to the completion of the drainage contract. There is another large plant of pumping machinery on the 980-ft. level in the Wolftone that has been under water for a number of years. When the water has been lowered to this point, it is proposed to repair the 'drowned' machinery and pump the flow by it directly to the surface. The draining of the Wolftone is regarded as one of the most important enterprises that have been undertaken at Leadville this year. The strong market now prevailing for zinc and lead sulphide ores, and the sharp advances being made in the price of silver have created an unprecedented demand for the huge deposits of ore that have been under water in the Wolftone shaft for years. It is known that the sulphide zone in the Wolftone and other holdings of the Western Mining Co. is equally as rich and extensive as the carbonate. Many millions of dollars have been taken from the Wolftone as carbonate of zinc, and an equal quantity should be extracted. The influence of the Wolftone drainage will not only affect the property itself but will also unwater the richest section of the district. The holdings of the Empire company are authoritatively stated to be the richest lead and zinc mines here. Immense bodies of this kind of ore are now being mined above the 600-ft. level. Last month $50,000 worth of lead and zinc sulphide was shipped from the property. These upper stopes are small in comparison to those known to exist throughout the lower workings. Output from these mines will be more than doubled as soon as the unwatering is complete.

VICTORIA, BRITISH COLUMBIA

New Mining Regulations.—Production of East and West Kootenay, Rossland, Ainsworth, Nelson, Boundary, Revelstoke, and Coast Districts.—Zinc.

Recent important occurrences here include two that are of more than ordinary interest to mining men: One is the change made in the law relating to the method of dealing with Crown-granted (patented) mineral claims forfeited for nonpayment of taxes, so as to facilitate acquirement of such claims by prospectors who shall do development work on them and find it to their interest to secure title to the property; the other is a decision by the Mining Committee of the Provincial Legislature that John Hopp, of Seattle, Washington, and his associates are fully entitled under the Placer Mining Act to leases granted to them of certain placer-gold ground at Bullion, Cariboo, which was for years the scene of the chief activities of the late John B. Hobson, who prior to 1906 established and operated for a Canadian company the largest hydraulic gold-mining enterprise in British Columbia, possession of which passed to the Guggenheim interests of New York and was afterward abandoned by them. At the end of 1913 the company that had been organized by the Guggenheims to acquire and operate the Bullion property sold to Robert T. Ward for $20,000 its assets which, however, did not include title to the ground, since failure to renew its free miner's certificate in 1912 had resulted automatically by law in forfeiture of the leases. Mr. Hopp and associates re-located the ground after it had been open to location nearly 18 months, and now they are confirmed in their title to it.

As to mining in East Kootenay, the only important producer among the metalliferous mines is the Consolidated Min-

ing & Smelting Co.'s Sullivan mine which, during the quarter ended March 31, shipped to the company's smelter at Trail 16,497 tons of ore, a small proportion of which was zinc ore, and by far the greater part lead ore.

In West Kootenay, Rossland mines continue to maintain their long lead in ore production over those of other parts of this extensive district. The total quantity of gold-copper ore shipped to Trail during the first quarter of the year from Rossland mines was 84,994 tons, of which 45,822 tons was from the Consolidated Co.'s Centre Star group, 35,308 tons from the same company's Le Roi mine, and practically all the remainder from the Josie group of the Le Roi No. 2, Ltd. Production of silver-lead ore in the Slocan mining division amounted to 3195 tons during the quarter; about one-half of that quantity was from the Standard mine near Silverton, with the Galena Farm, Hewitt and Lucky Thought, in the same part of district, and the Noonday, Reco, Rambler-Cariboo, Ruth, and Slocan Star, in central Slocan, and half-a-dozen smaller shippers in various parts of the district, also contributing to the above-mentioned total, which was the amount of silver-lead ore and concentrate received at Trail. Shippers of zinc concentrate to United States reduction works were the Galena Farm, Hewitt, Lucky Jim, Rambler-Cariboo, Ruth, and Slocan Star. Additions of machinery and plant are being made to the Slocan Star concentrating mill, and enlargement of the custom concentrator at Rosebery, Slocan lake, is being arranged for.

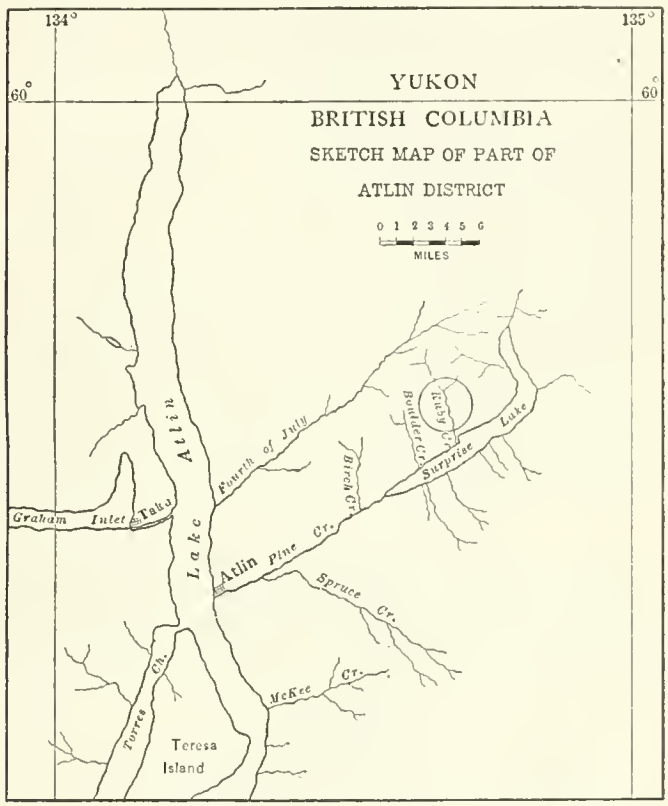
Ainsworth, with a total of 5212 tons shipped to Trail, and Nelson with 708 tons, are other West Kootenay divisions. In the former, the No. 1 with 2381 tons of silver-lead ore and the Bluebell 1968 tons of lead concentrate, were the larger shippers; the list also includes the Florence, Highland, Utica, and several others. In Nelson division, the chief production was by the Hudson Bay mine, which shipped oxidized zinc ore to the United States, while the Emerald sent 436 tons of lead ore to Trail. The Queen and Granite both milled gold ore; the Eureka shipped copper ore to Trail after having been off the list of producers for a number of years.

Of the several zinc-reduction projects that have had newspaper notice only one—that of the Consolidated Mining & Smelting Co. at Trail—has made actual practical progress in Kootenay district. The production of electrolytically refined zinc on a commercial scale is an accomplished fact at Trail, where the newly-erected and equipped refinery is now in regular operation. It has been announced that preparations for making sulphuric acid are being advanced by the Consolidated company, and that its plans for the electrolytic refining of copper will shortly be carried out.

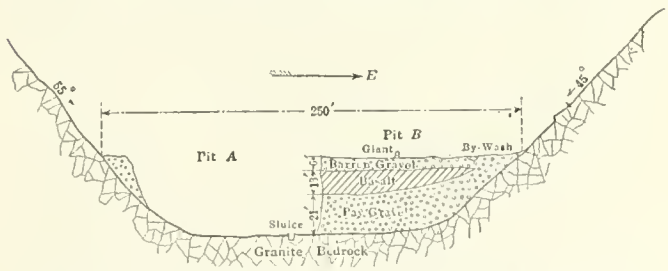
In Boundary district, the Granby Consolidated company now has all of its eight blast-furnaces at Grand Forks in full operation, after having had two out of commission through the winter season. At Greenwood, the British Columbia Copper Co. recently blew in a second furnace, having arranged for a sufficient supply of ore to admit of this extension of smelting operations. Milling gold ore at the Jewel mill, by the lessees of that company's property, was to be undertaken in April. Hauling ore from the Union mine, in Franklin camp, will be resumed as soon as the wagon road will stand the heavy traffic. In Camp Hedley, Similkameen, the customary progress is being made at the Nickel Plate gold mine and 40-stamp mill.

In the Coast district, the Britannia Mining & Smelting Co. continues to carry out an extensive plan of development of its Howe Sound copper mines, and is mining and concentrating about 1500 tons of ore a day. The Tonopah-Belmont Development Co. has acquired and is further developing the Surf Inlet gold mine, Princess Royal island. The Granby Consolidated Co. is operating to present full capacity its copper property at Hidden creek and smelting works at Anyox, Observatory inlet. The Rocher Deboule company, which in the second half of last year shipped to Anyox about 17,000 tons of 8% copper ore, is now shipping to Tacoma, Washington, and the Silver Standard, also near Hazelton, Omineca division, is sending some silver-lead ore to Trail.

'The Solution of Some Hydraulic Mining Problems on Ruby Creek, British Columbia,' is the title of a paper written for the Arizona meeting of the A. I. M. E. by Chester F. Lee and T. M. Daulton of Seattle. This district is 17 miles east of



Atlin. Gold was found there in 1898, and the output to date from placer mines is $4,518,000. The great width of the deposit, (250 ft.), flood-waters, poor pumping facilities, and large boulders were the difficulties. These were overcome by dividing the ground up the creek into two series of pits. First one was sluiced for 400 ft., then the other was started, working alternately. The boulders are blasted when the pits become too full of them. In the flood season only one pit is



CROSS-SECTION OF RUBY CREEK SHOWING POSITION OF GRAVELS BEING WORKED BY HYDRAULICKING.

worked, an arrangement of sluices allowing the excess water to go to waste. The gold-saving sluice-boxes, 42 in. wide, are lined with carbon-steel (0.9% carbon) plates, in place of spruce blocks used previously. After a season's wear (150 days), when 67,940 cu. yd. of gravel flowed over them, the plates showed an abrasion of 1/32 in. In 1915 6380 boulders were drilled and blasted and 21,955 'bulldozed' without drilling. In two years the average was one boulder for 2.5 yd. of gravel moved. Sullivan DA-19 40-lb. hammer-drills are used. All costs in 1915 totaled 47.6c. per cu. yd. The property is owned by the Placer Gold Mines Co. of Seattle, in charge of T. M. Daulton.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

'Wireless Service in Alaska' is the title of an article in the April issue of *The Wireless World*, of London, England. A brief though good description is given of the Territory, noting that progress is impossible without rapid means of communication. The cable and telegraph service is frequently interrupted on account of storms and volcanic disturbances. The Government, as well as mining and fishing companies have erected several wireless stations. The Marconi company has semi high-power installations at Juneau and Ketchikan, 250 miles apart. These have regular service with Astoria and Portland. The towers for the aerials in Alaska are 300 ft. high. The wireless conditions in Alaska are peculiar, due possibly to the geographical shape of the country and the continuous daylight during the summer months.

Juneau

On the west side of Funter bay the Alaska Gold Mining Co. has 17 men at work, this number to be augmented to 200 during the summer. A bunk-house of this capacity is to be built. Proposed work is a 5 by 18-ft. shaft to 600 ft. depth, and a 9 by 12-ft. adit 1500 ft. long. W. S. Pekovich is superintendent.

ARIZONA

Cochise County

During the quarter ended March 31 the Shattuck-Arizona produced 4,682,691 lb. copper, 1538 oz. gold, and 8965 oz. silver, with a net profit of $781,380.

Gila County

(Special Correspondence.)—Pending the delivery of the electrical equipment for the power-plant at the Eureka shaft, and of additional electric pumps, the Arizona Commercial Copper Co. is limiting operations mainly to stoping ore on the 13th and 14th levels of the Copper Hill mine. Daily shipments to the Old Dominion smelter average 150 tons of sulphide, most of which is smelting ore. The most important development under way is a raise to connect the 1200 and 1000-ft. levels at Copper Hill. This raise has been carried up 130 ft. in ore, the quality of which is steadily improving. It is apparently a continuation of the sulphide orebody below. At the Eureka shaft the 8th level is being opened, and the superintendent, Robert Boyd, states that the indications there are good. Some silicious ore from the Eureka is being shipped to the Copper Queen smelter at Douglas. It is expected that about $75,000 worth of new equipment, including electric pumps, turbines, boilers, compressors, etc., will be installed by June 1. At present about 800,000 gal. of water must be cared-for daily. The company's best ore is on the 1400-ft. level. The shoot, an extension of the Old Dominion vein, is widening as development continues east, the last stope showing a width of 40 ft. of ore.

Globe, May 2.

Silicious ore is again being sent from the Live Oak mine at Miami to the International smelter.

Mohave County

According to S. S. Jones, who recently resigned as superintendent of the Tom Reed mine at Oatman, the deepest workings are at 1400 ft., the total openings are 30,007 ft., and gold output to date approximately $6,000,000.

The Gold Ore mine is sending from 20 to 30 tons of $34 ore to the Gold Road mill daily. This comes from the 530-ft. level.

Extensive development is under way at the Oatman Amalgamated, Oatman Combination, Ivanhoe, Lucky Sam, Big Jim, Gold Dust, Arizona Tom Reed, Tom Reed Junior, Sunnyside, and United Western, and from which encouraging results are reported.

Pinal County

While sinking its main shaft the Ray Hercules company opened rich copper carbonate ore.

Yavapai County

Although the United Verde smelter at Clarkdale is treating 2500 tons of ore daily, it is not at full capacity. The monthly copper output is over 5,000,000 lb.

ARKANSAS

Sebastian County

At Fort Smith the Fort Smith Spelter Co. is making good progress in building its new smelter, hoping to complete it by July. In the four blocks will be 640 retorts each, a total of 2560. The cost is $250,000.

Across the river from Fort Smith at Van Buren, Crawford county, a smelter with four blocks of 800 retorts each is to be constructed by a New York metal house.

CALIFORNIA

Amador County

The club-house erected by the Plymouth Consolidated company for its employees was opened last week. Suitable addresses were made by Albert Burch and James F. Parks of the company.

Calaveras County

(Special) Correspondence.)—On Carson Hill W. J. Loring is making a large amalgamation of claims. He has an option on the Calaveras Consolidated, which was worked by an English company on a small scale many years ago. Systematic trenching and sampling of the property, which covers 8000 ft. on the strike of the lode, has given good results. An orebody 1700 ft. long and 15 ft. wide, averaging $3.50 per ton, has been disclosed. This will give a healthy margin of profit, as the neighboring mine, the Melones, is operating on $2.40 per ton. The latter has an adit from the Stanislaus river that reaches a depth of 1300 ft. below the outcrop, and has workings extending to a maximum vertical depth of 2650 ft. from the surface. It is obvious, therefore, that a consolidation of properties should be advantageous to all concerned.

Carson Hill, May 4.

Eldorado County

Between Placerville and Plymouth in Amador county, a distance of 23 miles, there is a good deal of mining activity along the Mother Lode, according to Burr Evans. Operations at Plymouth are so well known as to need no further comment. Nine miles north is the Laus Padre mine, a former rich producer. At Nashville the Montezuma shaft is being sunk to 1200 ft. Three miles south of this is the Amador Star, being developed by English capital. At the shaft, down 150 ft., a complete equipment has been erected. Sinking proceeds at the rate of 100 ft. a month to the 700-ft. point. Seattle and San

Francisco people have acquired the Teddy Bear and Union mines, respectively, near the Laus Padre.

MARIPOSA COUNTY

Los Angeles and Chicago capital has acquired the Mt. Gaines gold mine, 4½ miles east of Hornitos, with Samuel J. Paul in charge. The Mt. Gaines Gold Mining Co. took control on May 10. The mine is opened to a depth of 1300 ft., with stopes to 900 ft. It is full of water. A 5 ft. vein worth $7 per ton is said to have been left. An electric hoist and 20-stamp mill are part of the equipment.

After liquidating a debt of $73,700 and making many improvements to its power and treatment plants, the Mountain King company had a balance of $36,229 on March 31, 1916. An initial dividend of 3c. per share is to be paid on May 15. An assessment realized $60,000. Ore treated (28,145 tons) yielded $6.39 per ton, the recovery being 93.16%. The net earnings were $87,303. Ore reserves are sufficient to supply the 20-stamp mill for two years. Development amounted to 3765 ft. Standard Oil officials are interested in this concern.

SHASTA COUNTY

The new dredge of L. Gardella has started digging three miles south-west of Redding, on Clear creek. A good deal of the machinery came from Oroville.

TUOLUMNE COUNTY

(Special Correspondence.)—Operations on the App, and Dutch Sweeney mines are proceeding most satisfactorily. Options for 10 months on these two group of properties were taken by W. J. Loring on behalf of Boston capitalists on November 1, 1915. It was agreed to do 3000 ft. of development work on the two properties. To date 1600 ft. has been done in the App mine and 800 ft. in the Dutch-Sweeney group. The 1500, 1650, and 1800-ft. levels from the Dutch mine have been extended into the App, with cross-cuts and raises. Likewise, the North drift on the 1650-ft. level has been extended into the Sweeney claim. The result of this work has been to open up fully 200,000 tons of ore, averaging $4 or better. A 20-stamp mill has been at work since February 14 for the purpose of sampling the properties on a working scale. This mill treats 200 tons of ore per day; the average stoping width is 20 ft.; the maximum width of lode is 38 ft. These mines were worked heretofore for $1.75 per ton, with a small overhead expense. It is estimated that they can be worked to include all expenses for $2.50 per ton. It is likely, therefore, that the option will be exercised when it expires, at the end of August.

Sonora, May 4.

(Special Correspondence.)—The Nyman Consolidated Mines Co. held its annual meeting in San Francisco on April 17. When the company was incorporated in March, 1915, the question of finance was the first problem. Since then 119,785 shares of the 200,000 to be issued have been sold at $1 each. When the property at Jamestown was acquired underground work done amounted to 12,000 ft., the previous owners extracting 100,000 tons yielding $2,000,000. In July last year the mine was unwatered. Eventually the Mascot orebody was leased, this proving the most profitable system of working. The recovery was $17.20 per ton. During the last 9 months the Mascot, Knox & Boyle, and Nyman orebodies produced $31,092 from 5525 tons. The total cost was $2.50 per ton. The financial statement shows that on March 31, 1916, there was $19,146 cash in banks.

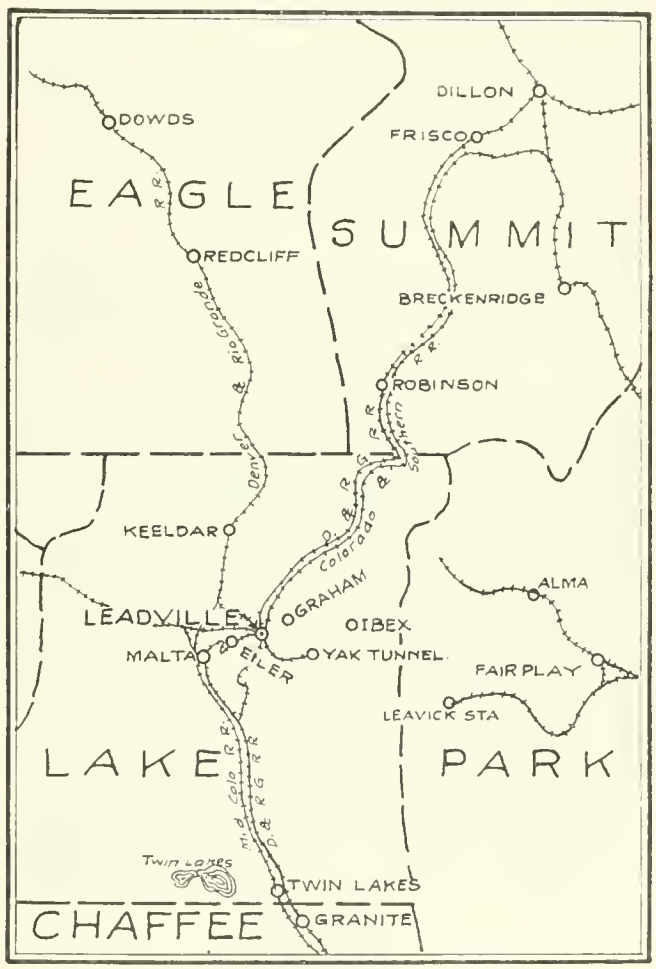
COLORADO

BOULDER COUNTY

The Crise Bracken tungsten mines above Boulder Falls have been acquired by A. H. Carlisle of New York for $100,000. The first payment of $25,000 was made last week. The Catastrophe mine is also under option for $60,000.

CLEAR CREEK COUNTY

(Special Correspondence.)—The boilers at the Doric adit on Saxon mountain, were fired this week. The bore, which has a length of 3009 ft., is to be driven to the Ruler vein. Driving will then follow to make connection with the east drift from the Capital adit.——Shipments of ore were started this week from the Josephine mine in West Argentine. Stephens brothers, the lessees, have 200 tons of lead and zinc concentrate and 100 tons of smelting ore ready for delivery to the Georgetown sampler.——Heavy shipments are going out from the Smuggler mine on Brown mountain. The ore is high grade, and gives a mill settlement of nearly $100 a ton in silver and lead. A. E. Simpson is manager.——The Wide West mine on Leavenworth mountain, recently taken under lease by A. L. Stephens,



PART OF COLORADO.

will be on the list of shippers during the present month. The many old workings have been cleaned out and re-timbered, and a 4-ft. body of galena is exposed that is worth $15 a ton in silver and lead.——Work was resumed this week on the Tobin mine in East Argentine. A new adit is to be driven to intersect the Wheeling vein with a view of determining the source of tungsten float that has been found in that vicinity. ——The Kitty Ousley property has been leased to S. E. Herber, work having been started a few days ago. The adit is being repaired and shipments of a lead-zinc ore will be started within a short time.——Development is under way at the Santo property situated on Saxon mountain. The adit now 1000 ft. long, is to be advanced.——A total of 12 sets of lessees are at work in the Capital mine, and regular shipments are being maintained by 10 of them. The ore is generally of a smelting grade, and mills from $20 to $70 a ton in gold, silver, lead and copper.——R. F. Staley of the Combination mill at Idaho Springs, has just installed two Empire tables. Ore is being treated from the Comstock and Specie Payment mines.——A. Freedman has disposed of his one-half interest in his lease on

the Edgar mine to the Boston Leasing Co. The ground is producing at the rate of 25 tons of $10 ore daily.

Idaho Springs, May 2.

(Special Correspondence.)—The general manager of the Imperial mines, E. J. Wilcox, reports the finding of a large body of rich tellurium and gray copper ore in its property in East Argentine, in an adit that had not been operated since 1907. The portal of this adit is near where the discovery of 60% tungsten ore was made last fall, but which has not yet been followed up on account of the deep snow.

Georgetown, April 30.

Lake County (Leadville)

Only 10 ft. of water remains in the Penrose shaft of the Down Town mines. A large station-pump is to be installed on the bottom level when the water is out.——Owing to the drainage work by the Down Town company, and the higher price of metals, the old Cloud City and Home Extension mines, long idle, will be re-opened in charge of Clarence Jarbeau.

Preparations continue for the unwatering of the east Carbonate Hill territory through the Mikado shaft. G. O. Argall is in charge.

The Western Mining and Empire Zinc companies have agreed on lowering the water in the Wolftone shaft 180 ft., thereby draining the Robert Emmet mine of the Empire.

Teller County (Cripple Creek)

The district's gold output in April is estimated at $1,199,585 from 87,475 tons of ore. The Roosevelt drainage-tunnel has entered another water-course, 300 ft. east of the Elkton shaft. The additional flow was 2000 gal. per minute.

At certain seasons gas is troublesome in Cripple Creek mines, interfering with operations. For the Arizona meeting of the A. I. M. E. George A. Burrell and Alfred Gauger have prepared a 21-page article on the composition of the rock-gas of the district. Over 30 miners have been killed by this gas in the past 25 years, while many others have been incapacitated for some time through it. No gas occurs in the oxidized zone, but is found at depth. The outside atmospheric pressure materially affects the outflow of gas into the mines. The gas is confined to the rock under low pressure. Detailed discussions are given of samples of gas collected in the Anaconda, Cresson, Mary McKinney, and Midget mines. The gas averages 14% carbon dioxide and 86% nitrogen. The acetylene lamps should not be used as the only warning against the presence of gas in these mines.

IDAHO

Boundary County

(Special Correspondence.)—The hills are full of prospectors now, some good men being among them. As the spring is well on all the small properties are resuming operations. The Deer Creek Mining Co. has purchased a cyanide-plant, and expects to start work on May 15.

Bonners Ferry, May 1.

Shoshone County (Coeur d'Alene)

During 1915 the Marsh Mining Co. at Burke made a loss of $63,791. Large expenditure was made at the mine and mill. The revenue for the first quarter of 1916 reduced the debt to $32,000. The mill feed averaged 5.5% lead in March, when 400 tons of ore and concentrate was shipped. Zinc concentrate has also been produced.

For three years miners and homesteaders in the Pine Creek district have been arguing over the rights of mineral claims. The Land Office ruled that certain ground was agricultural. In the Heim (homesteader) *v.* Boyle (prospector) suit, the Secretary of the Interior has decided in favor of the latter. A re-classification of land is wanted.

The Caledonia company made a profit of $263,033 in the first quarter from 11,646 tons of ore.

MISSOURI

Jasper County

There was a decline in ore prices in the Missouri-Kansas-Oklahoma region on April 30. The output was 7231 tons blende, 462 tons calamine, and 1144 tons lead, averaging $98, $74, and $100 per ton respectively. The total value was $859,179; and for 14 weeks $14,830,916.

One thousand acres of land west of Webb City has been acquired for 15 years by J. Ittlegel and F. M. Burch of Joplin. This is the largest lease ever reported in the south-west. The property will be thoroughly prospected.

A flotation plant is being constructed by the American Zinc, Lead & Smelting Co. at its Vogey mine. The process supplements the sludge and slime tables. The mine produces 7000 tons of ore a week.

Good progress is reported in the erection of a 400-ton mill at the Milton mine, north of Carterville. G. W. Field of the National Zinc & Lead Co. is interested.

In *The Mining Magazine* of London for April, H. Foster Bain, until recently with the Press, discusses the Joplin ore-deposits, including the views of other geologists. Mr. Bain's opening sentence is as follows: "Joplin is 'the town that Jack built,' 'jack' being the Missouri miners' name for sphalerite or zinc-blende."

MONTANA

Beaverhead County

Cyanidation of the Bannack Gold Mining Co.'s ore at Bannack will recover 97% of the gold and 70% of the silver, according to tests. The process includes all-sliming. The 150-ton mill should be complete by July 15. In the mine is 200,000 tons of ore developed.

Fergus County

(Special Correspondence.)—Prospecting is active this spring in the Judith and Moccasin mountains, the high price of metals having stimulated development.

At the Gold Acres claims at New Year in the Judiths, three bodies of low-grade ore have been disclosed, one of which is reported to be 18 ft. thick. Further work is being done in order to ascertain the extent of the orebodies.——At the Copper King property development now being done shows an orebody 65 ft. wide, which is said to have been traced over 1500 ft. on the surface.——At Maiden the Spotted Horse mine and mill employs 35 men. Ore as low as $3 a ton can be treated in the new cyanide mill, while before it was built no ore worth less than $20 would pay to ship to the smelter.——The Cumberland, McGinnes, and Whiskey Gulch mines near Maiden have been leased. Development is now being done at the Cumberland and will soon start at the others.——The gold ores of the Judiths occur in replacement deposits in limestone, near the contact with laccolithic intrusions or under sheets of porphyry. Mining is usually cheap and profitable. The lead-silver ores on the other hand, occur in small pockets or narrow veinlets, and while high-grade ores can sometimes be found, yet the quantity of such is usually too small for profitable mining. The increase in the price of metals, however, has permitted these ores to be mined at a profit, and several men are now sacking and shipping lead ore. Most of it comes from small prospects on the north and east sides of the mountains.

The Barnes-King Development Co. will spend $10,000 this summer on improvements on its power-plant on Warm Spring creek.——The adit on the North Kendall property is in over 500 ft., and according to W. C. Kruse a body 35 ft. thick has been cut that assays well in gold for cyanidation.

No mine has ever been developed in the south Moccasin mountains, although much prospecting has been done. Recent work on a group of claims, however, has disclosed a body of gold ore of grade suitable for cyanidation. Further work is being done in order to disclose the extent of the orebody.—— The foundations for the 700-ton gypsum mill of the Hanover

Gypsum Co. are completed, and the mill itself will be completed in about six weeks. Several carloads of gypsum have just been shipped to Seattle.

The Tenderfoot Mining Co. expects to erect a concentrator at its property in Meagher county this summer.

Lewiston, April 27.

Another, the second, dividend of 7½c. per share, equal to $30,000, is to be paid by the Barnes-King company on June 1. The quarterly report issued briefly discusses the mines and finances.

Silverbow County

The Butte & Superior Copper Co. is now known as the Butte & Superior Mining Co. The April output was 16,500,000 lb. zinc, 270,000 lb. lead, and 325,000 oz. silver. The recovery was 93% in treating 54,000 tons of ore.

During the first quarter of 1916 the North Butte produced 5,740,193 lb. copper, 366 oz. gold, and 244,976 oz. silver. The surplus increased by $262,389.

The 22 operating shafts of the Anaconda company are producing 14,000 tons of ore daily, to be increased to 15,000 tons within a month.

NEVADA

Clark County

Large profits are being made by the Yellow Pine company at Goodsprings, and the dividend has been increased from 10 to 15c. a share, equal to $150,000.

Esmeralda County (Goldfield)

Agreements between the Jumbo Junior Mining Co. and the reorganized Booth and Jumbo Extension companies, allow the first-named to have vertical side-lines and deep exploration through the Velvet shaft respectively. Work will start at a depth of 800 ft. J. K. Turner is superintendent of the Junior property.

The April output of the Goldfield Consolidated is estimated as $222,000 from 30,400 tons, with a profit of $60,000.

Humboldt County

The Rochester Mines Co. expects to extract as much ore from the Codd block in its Crown Point claim as did the lessees, namely 19,300 tons yielding $344,585.

Thirty-five miles north-east of Lovelock, near Antelope Springs, D. Dawson and F. Summers have opened a cinnabar deposit.

Lincoln County

Since April 15 the Consolidated Nevada-Utah new mill has been working satisfactorily. The daily output of zinc concentrate is 70 tons. Flotation is being tried.

Lyon County

The Nevada-Douglas is sending copper ore to Utah smelters regularly, making a profit of $20,000 a month. The leaching plant of 250-ton capacity was expected to be in full operation on May 10. There are 175 men employed.

Nye County (Tonopah)

During the last week of April Tonopah mines yielded 8569 tons of ore worth $179,502.

Storey County (Comstock)

The old Union shaft has been overhauled to the 2400-ft. level, and an air passage is open to 2700 ft., improving ventilation. This shaft was sunk by James G. Fair, and abandoned in 1885. Its reconstruction is of importance to the workings in the Union, Sierra Nevada, and Ophir mines at the north end. Bullion extracted from ore mined since December 15, 1915, in abandoned territory was worth $191,412. Last week's ore included 87 tons of $57.15 ore from No. 4 stope above the 2400-ft. level. This was from the area not considered valuable years ago.

White Pine County

During the first quarter of 1916 the Giroux Consolidated's income was $101,961 from 18,537 tons of ore. The profit was $49,026, on which the bullion-tax was $613.

In the Press of April 1 it was stated that Millick brothers and J. Fox had jumped Hudson's location in the Minerva district. Hudson states that the former have treated him fairly, and of the $10,000 to be paid him they have made one payment.

OREGON

Jackson County

An election is to be held at Medford on May 23 to decide whether the town will issue bonds for $300,000 to help in constructing a railway to the Blue Ledge mines, 30 miles from the present terminal of the Bullis electric line. If carried, the road will eventually head toward the Pacific coast north of Trinidad in Humboldt county.

TENNESSEE

Polk County

Diamond-drilling from No. 8 level in the Tennessee Copper mine has passed through 400 ft. of a solid orebody. The acid plant at the smelter is again in full operation, after a two months' shut-down due to a strike.

TEXAS

Llano County

(Special Correspondence.)—Attention of late has been directed to the mineral resources of the Llano region. Several promising mines are being opened, and preparations made for extensive exploration. Twelve miles from Llano is a large deposit of manganese ore, from which 2800 tons was shipped recently. Auto-trucks haul the ore to the railroad here. Some tungsten ore is to be developed. Extensive deposits of iron ore occur. The Iron Mountain property has been explored by drilling and underground work. Near Llano, in Burnet county, is a good deal of fluorite. Molybdenite is being mined near Llano. The Heath, the only producing gold mine in the State, is 5 miles east of Llano. A large plant was erected, but it is closed at present. McCarty Moore of Dallas and others are owners. There are possibilities in asbestos and copper. A graphite deposit in the Burnet area is being developed.

Llano, April 29.

UTAH

Piute County

A revival is reported from the Marysvale district, many old claims being re-located. Minerals produced are antimony, copper, gold, and manganese.

Salt Lake County

Utah Copper miners are to receive an advance of 25c. per shift, while at the mills the increase is from 15 to 25c. per shift, while copper is 25c. per lb. or over.

At the South Hecla Extension mine in the Little Cottonwood the progress in driving for three fissures is 125 ft. per month on one shift per day, using machines.

Summit County

On account of the rise in silver the Silver King Coalition company at Park City has raised wages from 25 to 50c. per shift.

WYOMING

Albany County

The Rambler lode platinum mine at Holmes is to be actively worked by the Platinum Mining & Milling Co., which has a lease on the property from the Rambler Copper & Platinum Co.

Francis W. Bacon is consulting engineer. Last October 49 tons of ore sent to Irvington, N. J., yielded 6.28 oz. gold, 74.65 oz. silver, 76.2 oz. platinum, 26.42 oz. palladium, and 3046 lb. copper, worth a total of $2686, when all metals were low.

CANADA

British Columbia

Rich gold ore has been opened in the Fawn mine in the Sheep Creek district. A 5-stamp mill on the adjoining nugget claim is to be used to crush the ore.

At 700 ft. depth in the Queen mine near Salmo a lode of free-milling gold ore 30 ft. wide has been opened.

The Princeton district is to be more active than in years.

To develop a property near New Hazleton the Spokane-Rocher De Boule Mining Co. has been formed. A 1000-ft. adit is to be driven. Ore being extracted assays 7% copper, $2 gold, and 15 oz. silver per ton.

A New York syndicate, headed by Hayden Stone & Co. and D. C. Jackling, has acquired control of the Hudson Bay zinc mines, seven miles from Salmo, for approximately $1,125,000, according to H. T. Irvine of Spokane. Without waiting for completion of the negotiations the Hayden-Stone syndicate took possession of the Hudson Bay company's property through J. L. Bruce, general manager of the Butte & Superior company. Plans for its development and equipment will be put into execution at once. They include the construction of a railroad 9 miles long from the Nelson and Fort Sheppard branch of the Great Northern line at Salmo, to a point on Sheep creek, near the mine, where a large concentrator will be built. From this point they will immediately start to drive an adit which will cut the vein 1700 ft. below its outcrop, or approximately 1000 ft. below the cross-cut adit which Cullen and Bacon started, and which also will be pushed to completion. To expedite all this work a complete equipment of machinery will be provided forthwith. With a view to putting the property on a large producing basis an aerial tramway will be immediately constructed from the mine to the terminus of the proposed railway, and a line of motor vehicles put on to handle the ore from that point to Salmo until the railroad can be got into operation. R. K. Neill will remain in charge of the mine under the direction of Mr. Bruce.

Ontario

The last yield of the Hollinger was 41,423 tons of $9.04 ore, with a profit of $151,303. The Hollinger, Acme, and Millerton companies and claim 13,147 of the Canadian Mining & Finance Co. are to be amalgamated with a capital of $25,000,000, under the name of the Hollinger Consolidated Mines, Limited.

At Porcupine the Dome continues to increase its production, which for the first quarter of 1916 amounts to $513,451. The output for March was $176,590. With the increase of milling capacity expected from the installation of three Hardinge ball-mills and other improvements, it is anticipated that this year's production will be nearly $2,500,000.——The annual report of the Dome Lake showed receipts of $80,707, and expenditure $74,980. The 10-stamp mill treated 11,827 tons of ore, averaging $9.12 per ton, with an extraction of 79.98%. The cyanide-plant is now ready for operation. Underground development gave encouraging results, ore assaying as high as $30 per ton having been opened on the third level.——At the Schumacher four quartz veins have been cut on the 600-ft. level, which will yield good milling ore. The mill is treating about 135 tons daily.——During the three months ended March 31, the Porcupine Vipond produced $53,348 from 11,810 tons of ore, of the average value of $5.24 per ton. Working costs were $4.53 per ton. Ore reserves are estimated at 91,000 tons, containing gold valued at $688,591.——The La Rose of Cobalt, has sunk a shaft on the Maidens-McDonald properties 50 ft. deep, at which point the vein divides into two parts, one 10 ft. and the other 5 ft. wide. Another shaft will be sunk and trenching done.——The shaft being sunk by the Triumph Mining Co. on the Success, just south of the Schumacher, is down 200 ft., where a level will be driven and the shaft sunk farther.——The shaft at the Jamieson claims, now being worked by Chisholms Corporation, is down 40 ft. with visible gold all the way.

At the McCane property, Kirkland Lake, which is under option to the Beaver Consolidated, the shaft is down over 200 ft., with a station cut at 175 ft. The vein dipped out of the shaft at 110 ft.——The McIver Gold Mines is sinking at the

TRAIL TO THE ST. MAURICE MOLYBDENUM MINE. W. E. SIMPSON LOOKING ON SNOW 7 FT. DEEP.

Oakes claims in the Beatrice Lake section, where there is some free gold showing.——Active exploration is under way at the Swastika, which has been pumped out and sampled.——The Lucky Cross in the Swastika district is being worked under option by the Trethewey of Cobalt.

The properties of the Porcupine Independence, consisting of nine 40-acre claims in Jamieson township, have been taken over by a Boston syndicate represented by Albert Sutcliffe & Company.

During March the Kerr Lake mine produced 214,920 oz. silver.

The general manager of the Crown-Reserve Mining Co., Samuel W. Cohen, reports as follows on the results of this Cobalt property during 1915:

Low prices for silver affected profits and costs. The Provincial government removed the necessity of paying royalty. Development totaled 3387 ft. Kerr lake was drained completely, the total water and mud being 700,000,000 gal. The new area opened by the work was not as prolific in veins as had been hoped, but results were satisfactory on the whole, and made it possible to extract known ore containing over 2,500,000 oz. silver. The job paid for itself. Work has been started on the north vein at 500 ft. under the diabase sill. Mining cost 25.48c. per ounce.

The output of high-grade and mill ore was 657,395 oz., making 19,086,536 oz. to date. Smelting and milling cost 16.58c. per ounce.

Total costs were 45.01c. The profit was $48,611. Dividends, from company's profit, that of the Silver Leaf and Drummond Fraction mines, and dividends from the Porcupine-Crown company, were $106,129, making $6,982,724 to date. The surplus is $269,997.

The company acquired under lease the Globe mine at Dedrick, Trinity county, California. The property is fully equipped and is a regular gold producer.

The Porcupine-Crown Mines, a subsidiary of the Crown Reserve at Cobalt, operates at Porcupine, and the manager, M. W. Summerhayes, reports as follows:

To a depth of 700 ft. development totaled 4569 ft. Diamond-

drilling in flat holes amounted to 2616 ft. So far as opened the ore-shoot is 465 ft. long on the 100-ft. level, 1062 ft. at 200 ft., 1189 ft. at 300 ft., 1097 ft. at 400 ft., 500 ft. at 500 ft., 20 ft. at 600 ft., and 30 ft. at 700 ft. Reserves are estimated at 150,000 tons worth $1,250,000. Quartz-porphyry probably limits the ore-shoot in the south. Faulting is somewhat troublesome. Underground work cost $2.93 per ton.

The mill treated 41,326 tons of ore and 5093 tons of old tailing, yielding $615,538, at a cost of $1.09, and with 97.7% recovery on the ore and 85.77% on the tailing. All costs were $6.09 per ton. The net profit was $330,649, of which $240,000 was paid in dividends. The surplus is $269,977.

MEXICO

The new mining law, mentioned in the last issue of this journal, went into effect on May 1.

Bullion, concentrate, and ore shipments from Mexico to Arizona in April totaled 10,185 tons worth ₱2,763,900. Of this Nacozari contributed 9396 tons, and El Tigre 234 tons.

JALISCO

(Special Correspondence.)—The Amparo Mining Co. and the Cinco Minas Co. of Etzatlán and Magdalena, respectively, are the largest operators in this State, and the only mines that have been able to keep running through the various difficult periods of changing governments, bandits, and lack of transportation. The smaller properties are unable to work under existing conditions. The richer ore from idle mines is being extracted and treated on a small scale by *buscones*. Nearly all of the former miners and miner-revolutionists are anxious to work, but unless the operations are large enough to maintain a guard at the mine, there is a continuous risk of robbery or worse at the hands of small bands of bandits that travel in the guise of Villistas, or without pretense of being anything else but bandits. The Amparo company has sent 125 lb. of slime to the United States for making flotation tests.

Guadalajara, April 24.

Schools and Societies

The seventy-eighth ordinary meeting of the FARADAY SOCIETY was held on March 15 at the Institution of Electrical Engineers, London. The meeting was devoted to an informal discussion on 'Methods and Appliances for the Attainment of High Temperatures in the Laboratory.'

The TEXAS STATE SCHOOL OF MINES at El Paso has commenced publishing a quarterly called 'The Crucible.' We hope it will improve on the first number, as most of the material is to be found in the principal technical journals, but the editor says the booklet is to be a "melting-pot."

Its fifty-third annual commencement exercises are to be celebrated by the UNIVERSITY OF CALIFORNIA in the Greek Theatre at Berkeley on May 17. The alumni entertain the 1250 who are to receive degrees and the guests of honor at a commencement luncheon in Strawberry canyon immediately afterward. The six weeks' summer session opens on June 26.

During the past month the senior miners and geologists in charge of B. L. Miller of the Department of Geology, and Howard Eckfeldt of the Mining Engineering Department of LEHIGH UNIVERSITY made inspection trips to various mining districts in Pennsylvania and New Jersey. At Cornwall, Pa., the mine and mill of the Cornwall Ore Banks Co. were visited, and opportunity afforded to study the fine example of contact metasomatism found at this place. Mt. Hope, N. J., was visited, and the mine and mill of the Empire Steel & Iron Co. were seen. At Franklin Furnace, N. J., two days were spent studying the mining methods, milling, and geology of the district. One afternoon was spent at the new workings at Stirling Hill.

PERSONAL

Note: The Editor invites members of the profession to send him particulars of their work and appointments. This information is of unquestioned interest to our readers.

W. J. LORING is at Boston.

WALTER STRACHE sailed for Europe on May 3.

JOHN SEWARD of New York is in Nova Scotia.

R. M. GEPPERT has returned to London from El Oro.

DONALD F. FOSTER has returned from Egypt to London.

BEN. B. LAWRENCE is expected shortly in San Francisco.

R. GILMAN BROWN left London for Petrograd on April 22.

J. PARKE CHANNING has been examining copper mines in Cuba.

WILLIAM E. FENWICK of Detroit is mining copper in western Cuba.

C. B. LAKENAN has been visiting the Utah Copper mine at Bingham.

E. F. GORDON, of the Primos M. & M. Co., is at Globe, Arizona, for a week.

R. B. LAMB is in the Oatman district. He will be there several weeks.

W. C. MADGE and ALFRED TELLAM are at the Ridder mine, in the Altai, Siberia.

HENRY W. HAYDEN has obtained an appointment with the Seoul Mining Co., Korea.

BERNARD H. LASKY of Kennett, California, is examining properties on the Mother Lode.

W. W. MEIN will sail from Cape Town on May 13, returning to New York by way of London.

JOHN ADAM has been appointed manager of the Great Fingall Consolidated in Western Australia.

MAX. J. WELCH sailed from New York to South America on May 6, to be away for several months.

MALCOLM J. MACLAREN is making a geological study of the Oriental Consolidated mines, in Korea.

GEORGE DES ROCHERS of Michigan is on the engineering staff of the Nevada Consolidated Copper Co., at Ruth, Nevada.

R. W. BROCK, formerly director of the Canadian Geological Survey, is major in the Seaforth Highlanders of Canada.

ROBERT A. KINZIE, accompanied by F. R. BURNHAM and H. J. MACOMBER, is examining tungsten and vanadium properties near Globe, Arizona.

COREY C. BRAYTON, C. E. GRUNSKY, JR., and E. L. OLIVER have been selected to represent mining engineers on the Conference Committee of Californian Engineers for Preparedness.

ALLAN J. CLARK, W. J. SHARWOOD, and B. C. YATES of the Homestake Mining Co. have been selected as representatives for South Dakota on the Naval Advisory Board.

FRANCIS CHURCH LINCOLN, Director of the Mackay School of Mines, University of Nevada, Reno, Nevada, will sail from New York on May 27, bound for Peru and Bolivia on mining business.

Obituary

PERCY E. O. CARR died at Saltillo, Mexico, on April 14 after a short illness, having contracted typhus while on a visit to Mexico City. He was manager for the Mazapil Copper Company, to the interests of which he had devoted himself with unwavering loyalty and courage during the protracted period of Mexican brigandage. A graduate of the Royal School of Mines (London), an engineer of unusual ability, a trusty friend, a devoted husband and father, Percy Carr will be mourned deeply by all who knew him.

THE METAL MARKET

METAL PRICES

San Francisco, May 9.

Antimony, cents per pound	39.50
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	$8.00—$8.80
Platinum: soft metal, per ounce	$85
Platinum: hard metal, 10% iridium, per ounce	$89
Quicksilver, per flask of 75 lb	$100
Spelter, cents per pound	22
Tin, cents per pound	50
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, May 9.

Antimony: 50% product per unit (1% or 20 lb.)	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	12.50
Manganese: 50% metal, 8% silica, per ton	12.00
Tungsten: 60% WO_3, per unit	15.00—55.00

The U. S. Geological Survey bulletin on chrome-iron ore, by J. S. Diller, has been published.

EASTERN METAL MARKET

(By wire from New York.)

May 9.—Copper is strong and moderately active; lead is dull and easy; spelter is also dull and soft.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

The upward bounds of the silver market have been checked by a considerable drop in two days. Imports of metal into England during the first quarter of 1916, 1915, and 1914 were 22,442,691, 26,105,164, and 22,449,046 oz.; while experts were 12,214,273, 20,795,907, and 29,267,060 oz., respectively. For the period of 1916 exports to India were 11,543,597 oz. less than in the same time of 1915.

Copper production of the United States in 1915 totaled 1,388,003,527 lb., compared with 1,150,137,192 lb. in 1914, according to the Geological Survey. Arizona was first, Montana second, Michigan third, Utah fourth, and Alaska fifth. Stocks at the end of the year were 82,429,666 lb., about half of those a year ago.

March yields were as follows: Chino, 6,333,255 lb.; Nevada Con., 6,565,559 lb.; Ray, 6,379,581 lb.; Utah, 12,714,651 lb. April outputs were: Anaconda, 33,300,000 lb.; Inspiration, 9,800,000 lb.; Old Dominion, 3,290,000 pounds.

The A. S. & R. Co. has declared its quarterly dividend of 1% and extra of ½% on common, and 1¾% on preferred shares. Copper Range pays $2.50 per share on June 15.

Tin is quiet at 50 to 51 cents.

The new smelter of the A. S. & R. Co. is producing 4 tons of tin daily. Within 60 days this quantity will be increased to 15 tons. Bolivian 'barilla' (concentrate) is arriving regularly.

The International Nickel Co. pays $2 (8%) a share on June 1, for the quarter ended March 31.

Eastern Metal Market

New York, May 3.

Copper has continued dull, but prices are strong and promise to remain so in view of the sold-up condition of the producers. Some re-sale metal has appeared, but not enough to weaken the market.

Zinc has declined, but the limit of concessions appears to have been reached. Inquiry by the galvanizers has been good since the last report.

Lead has ceased to decline, the leading interest and independents now quoting the same level at New York. The market has been exceedingly dull.

Tin is higher. Difficulty in obtaining licenses to ship from London continues the dominating feature of the market.

Antimony is lower. All efforts to arouse interest on the part of consumers have failed. The supply is abundant.

Aluminum is unchanged at 58 to 60c. per pound.

The steel and metal-working trades are hampered by new strikes which were declared May 1. Hardly a city in the East is not affected by labor troubles, despite general advances in wages, and the condition may not yet have reached its height. The total of pig-iron production in April was 3,227,768 tons, or 107,592 tons a day, against 3,337,691 tons in March, or 107,667 tons a day. New buying of steel products is lighter. There is a halt in the renewal of munitions' contracts, but the plants are working at full pressure on orders in hand. The machine-tool industry is in a healthy condition, except for the many strikes with which it is contending. Everywhere there is an acute shortage of labor and the unions are taking advantage of the fact.

COPPER

The market has continued very dull, and there is not much to report, except that the strength of quotations is unimpaired. Electrolytic for delivery in July and August is quoted at 29c., full terms, and September or later, about 28.50c. Prompt electrolytic has sold at 30.30c., full terms. Lake is unavailable in large quantity this side of September. The nominal quotation is 29 to 29.50c. Some re-sale metal is appearing on the market, offers to sell having been made by a few consumers who have more copper than their immediate needs call for. They would sell, then buy futures, and take the profit thus to be realized. Rumors are current to the effect that France is contemplating some large buying. Prior to the recent extensive sales there were similar rumors. The refineries are behind in their shipments. They have no strikes on their hands at the present time, but labor is scarce, and the freight situation has made it difficult for them to get materials. The London market for electrolytic has continued to gain in strength, the quotation yesterday (May 2) being £145. In April exports aggregated 19,980 tons. European statistics show that stocks in Great Britain and France have further increased. The stocks April 30 totaled 7223 tons, against 6807 tons on the 15th, and 5528 tons on March 31.

ZINC

Students of the zinc market firmly believe that while fluctuations are inevitable, prices generally will be fairly well sustained throughout the second and third quarters of the year. Of the last quarter they will not venture to predict. They do maintain, however, that when the war ends there will be a better margin of profit in spelter than there was prior to the outbreak of hostilities. On the whole the past few days have been quiet, although there was an excellent flurry of inquiry in the latter part of last week, a good deal coming from the galvanizers; but actual business was not as heavy as the inquiry would seem to justify. The market has turned firmer, and recessions in price are believed to be over for the present. Prompt was quoted yesterday at 17.50c., New York, and about 17.25c., St. Louis. May delivery was 17 to 17.25c., New York, June about 16.50c., and July about 16c. Futures are inactive, the faith of consumers having been spoiled by the report of the U. S. Geological Survey indicating a great increase in production. The Government's figures are considered excessive by the trade, although it is admitted the additional capacity will mean greatly increased production. It is conceded that Great Britain will make herculean efforts to establish on a large scale the smelting of Australian ores in England, with the hope of supplanting Germany in that industry. On May 1 the London market declined £6, but the drop is not regarded seriously here as it is recognized that the London market has been too high in comparison with that which has prevailed at New York. The quotation for spot in London May 2 was £98. April exports totaled 2211 tons.

LEAD

The decline in prices has been checked, with the New York quotation at 7.50c., and that at St. Louis 7.37½c. The A. S. & R. Co., is asking 7.50c., New York, and 7.42½c., St. Louis. The tone of the market has changed from easiness to firmness, a change which the holders of lead brought about very easily. Their efforts to sell brought them nothing, and they ceased to press sales, whereon the market at once took on a better aspect. There has been no business worthy of comment in the past week so far as can be learned. April exports totaled 1372 tons. The London quotation May 2 was £34 10s.

TIN

Not much has been done in tin during the past few days, but in the deals completed the buyers have been those who usually are sellers. They were buying to cover their commitments to consumers, and in view of the higher prices now quoted their plight is a serious one. Their situation is the result of having sold futures at a time when licenses to ship from London were only obtained with the greatest difficulty. In fact the matter of these licenses has been the feature of the tin market for several months, and is the dominating feature of today. In the past week there has been good demand for April, May, and June positions, but sellers have been few. The New York quotation for spot on May 2 was 52.50c. Deliveries into consumption in April aggregated 4202 tons, of which 602 tons came to the East *via* Pacific ports. There was afloat on the 2nd, 3829 tons.

ANTIMONY

The market is plentifully supplied, but consumers cannot be interested, despite the fact that there have been substantial concessions in price. Chinese and Japanese grades are quoted at 37.50 to 38.50c., the American priced down to 36c., yet buyers hold aloof from the market. Needle antimony is offered at 20c. but is equally stagnant. The entire market is weak.

ORES

Antimony: Despite the weakness in antimony, antimony ore continues strong. Its price is supported by the fact that but little is being offered. The quotation is $2.70 per unit for 50% product.

Tungsten: The market is a nominal one with no prices obtainable. The notions of buyers and sellers as to the market are wide apart, and little or no business has been done. Ideas of what constitute the market differ several dollars a ton. The buyers are under the impression that the many offerings which have been brought out by high prices will eventually bring the market down.

COMPANY REPORTS

INTERNATIONAL NICKEL CO.

Nickel is used in armor-plate and other steels, munitions, German 'silver,' plating, and for many other purposes. The International Nickel Co secures most of its ore from the Creighton mine at Sudbury, Ontario, and refines the matte from its smelters in Canada at Bayonne, New Jersey. The matte is sent by rail, and contains 55% nickel and 25% copper. During 1915 the company's income was $7,230,760, against $6,566,787 in 1914. Holders of preferred shares received $534,756, and of common shares $4,753,937. The year's surplus was $309,778.

SEVEN TROUGHS COALITION MINING CO.

A financial statement of this Nevada company for 1915 shows the following:

Gold sold	$397,070
Other revenue	14,457
Total	$411,527
Operating expenses	215,066
General	23,587
Total	$238,653
Profit	172,871
Dividends (5)	180,381

The year commenced with a balance of $76,856, and ended with $69,024. Assets, including cash, bullion, etc., total $112,681. There are no liabilities.

HEDLEY GOLD MINING CO.

This company operates the Nickel Plate and Sunnyside mines, a 10-stamp mill, and an 1800-hp. hydro-electric power-plant near Hedley, British Columbia. The general superintendent, Gomer P. Jones, reported as follows:

Development amounted to 2784 ft. The Dickson incline in the Nickel Plate, was extended to 825 ft. At the 600-ft. level the orebody is 25 ft. wide, averaging $12 per ton. $13 ore is being mined in stopes at 700 ft. Below this, separated by an andesite sheet, is another valuable shoot. It is larger than that above, and worth $15 per ton. Diamond-drilling gave useful prospecting information. Ore reserves total 423,522 tons, assaying $10.39 per ton. In the upper part of the mine 12 cu. ft. equaled one ton, but at depth this is only 10 cu. ft. due to more arseno-pyrite. This resulted in a large increase of concentrate, so a system of total cyanidation is being adopted. General improvements in 1916 will cost $60,000.

The output was $796,592 from 74,265 tons of ore, or $11.65 per ton. Of the $371,746 profit dividends absorbed $300,000. The surplus is $435,070.

UNITED STATES SMELTING, REFINING & MINING CO.

This controls the U. S. Smelting Co., U. S. Metals Refining Co., U. S. Smelting, Refining & Mining Exploration Co., the Centennial-Eureka and Richmond-Eureka mining companies in Utah, the Mammoth Copper and Needles Mining & Smelting companies in California, the Gold Road Mines Co., in Arizona, and the Compañia de Real del Monte y Pachuca in Mexico.

The output of metals in the past three years was as follows:

Metal	1915	1914	1913
Copper, pounds	26,923,674	17,946,659	20,239,973
Gold, ounces	196,481	124,719	148,372
Lead, pounds	87,102,179	64,443,260	58,116,504
Silver, ounces	12,071,863	9,936,237	13,089,708
Zinc, pounds	34,105,471	.....	.....

To total amount of ore from the Centennial-Eureka, Mammoth, Gold Road, Tennessee, and Bingham mines, also mines in Mexico was 1,066,025 tons, of which the values of the metal contents were in the proportion of 30% copper, 5% lead, 21% zinc, 2.8% silver, and 19% gold. The Real del Monte mills were operated at 50 to 80% of their capacity, in spite of great handicaps.

The year's net profit was $6,592,324, plus $1,515,592 from 1914, a total of $11,107,916. Dividends absorbed $1,965,561, and reserves for depreciation $880,900, leaving $8,253,455 for 1916. Assets include $2,482,831 cash, and metals, ore, supplies, etc., $9,033,575; liabilities include accounts payable and payrolls, $935,727; drafts in transit, $712,304, and reserves for refining, etc., $1,283,225.

The past year was one of great and increasing prosperity for the company, the earnings being the largest in its history. Three zinc smelters were acquired in Kansas, and a mine in Missouri, at a total cost of $953,598. There were 786 properties offered for consideration; 655 were turned down, 118 had preliminary field examinations, and 13 were completely investigated.

BUNKER HILL & SULLIVAN MINING & CONCENTRATING CO.

This well-known Idaho company has been frequently discussed of late on account of its extra dividends and the great lead smelter to be erected at Kellogg. The report of Stanly A. Easton, the manager, is brief, but the statistical data is interesting and is best tabulated as below. Of the net available surplus of $1,819,888 dividends absorbed $1,062,750. The Caledonia and Sierra Nevada companies adjoining, and under Bunker Hill management, paid the latter $532,558 in dividends. On account of an unsatisfactory smelting contract with the A. S. & R. Co. the Sierra Nevada has not sold any ore since April 29, 1915. Both mines contain considerable quantities of ore. Reserves in the Bunker Hill mines total 3,573,930 tons. The Stewart company paid $15,000 in full settlement of ore removed from the Saxon claim. Exploration on No. 14 level of the Bunker Hill, 1000 ft. below the Kellogg tunnel, was generally satisfactory. Mr. Easton discusses the smelting company's charges, and the reason for the proposed smelter. While the cost of producing lead was 1.5c. per lb. at Kellogg in 1915, the same as in 1914, the smelting company's charge increased from 1.91c. in 1914 to 2.7c. per lb. in 1915. This was due to a modification of the contract expiring in June, 1915, which the smelting company refused to renew. Taking everything into consideration the new smelter at Kellogg is justified.

Some details of last year's work are as follows:

Exploration, feet	4,783
Average cost per foot	$7.317
Cost per ton:	
Stoping 455,205 tons	1.351
Tramming 455,205 tons	0.056
Hoisting 385,985 tons	0.047
Pumping	0.034
Underground improvements	0.024
General mine expense	0.433
Total mine charge, per ton	$1.999
Mills in operation, days	356
Ore concentrated, tons	441,854
Cost per ton:	
Crushing and conveying	$0.061
Screening and jigging	0.081
Grinding	0.050
Concentrating	0.076
Improvements and general	0.157
Total treatment charge, per ton	$0.425
Concentrate shipped, tons	59,424

Details of concentration will be given in another issue of

this journal. The revenue from silver and lead was $4,139,393; dividends and other income made a total of $4,802,033. The net profit was $1,725,442, of which $1,062,750 was distributed. The balance from 1914 was $3,245,475, and that carried forward to 1916 $3,691,166.

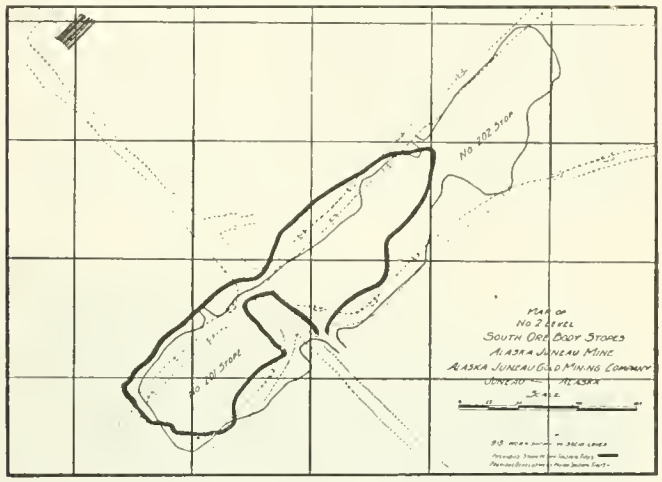
ALASKA JUNEAU GOLD MINING CO.

According to the president of this company, F. W. Bradley, by the end of 1916 the mine will be prepared to supply for treatment 8000 tons of ore daily. Practically all ore and waste removed during development in 1915 was sent to the 50-stamp 'pilot' mill, recovering $201,036 from 179,892 tons. Different machines were tested and a flow-sheet for the new mill devised. Practice at the Gastineau mill near-by, and the Inspiration in Arizona was studied, resulting in ball-mills being decided on for the main reduction and the Deister rougher and slime-tables for concentration. Contracts for machinery have been let, but on account of delays in winter the first unit will not be ready until March, 1917.

The secretary, G. D. Abbott, states that the cash on hand on January 1, 1916, was $2,232,123, sufficient to pay all obligations and bring the property to the point of treating 8000 tons a day. The revenue in 1915 was $253,483, and net loss $544,700, which is accounted for by the treasury stock sales expense of $544,760, interest, etc. In the treatment of 239,918 tons to date, producing 11,193 oz. gold bullion, 333 oz. base bullion, 151 tons of galena concentrate, and 1492 tons of iron concentrate, worth $270,426, the yield was $1.1272 per ton, from ore averaging $1.4483 per ton.

The general superintendent, P. R. Bradley, reported as follows:

An average of 301 men were employed at $3.52 per day. There was plenty of labor available. Co-operation in departments was commendable. Development amounted to 16,775 ft., against 5495 ft. in 1914. The most important work was done on the north orebody on No. 4 level, preparing it for an output of 8000 tons daily. The system of mining includes the undercutting of a section of the orebody about 700 ft. long by 250 ft. wide, driving intermediate levels, placing ore-chute raises and bulldozing chambers at regular intervals, and the driving of 18 raises from the back of the cut area to the level above. From these raises numerous powder drifts are to be driven for blasting and forcing the rock to cave as required. The chutes are 6 ft. wide with 3½-ft. clearance below the bead-blocks, and are fitted with arc-type gates. The drifts and Gold Creek tunnel were trimmed to allow of the passage of 10-ton cars to be used when milling commences. Work to be completed by September 1, 1916, totals 21,936 ft., of which 40.61% was done by December 31 last. Other work was done on No. 4 level, also some stoping above it to supply the mill and prepare for future work. Development proceeded on No. 2 level. In the first five months of 1915 all ore was sorted in the stopes. Machine-drill duty in stoping was 50.2 tons a



shift; in cutting out, 19.7 tons. Samples numbering 1329 from development averaged $1.04 per ton; the Aurora orebody on No. 2 level $2.09, and the north orebody on No. 4 $1.01 per ton.

The 50-stamp mill operated 318.33 days. With a ¼-in. screen the duty ranged from 11.2 to 19.7 tons per stamp-day, an average of 14.45 tons; through 8-mesh, 8.88 tons; and through 24-mesh, 5.77 tons. The average daily capacity was 565.09 tons. With all ¼-in. screens and Chilean mills the capacity would have been 900 tons. Lead concentrate was sent to the Selby smelter. The recovery from the iron concentrate, assaying $19.52 per ton, was 77.51% at the mill. This product was reground in a Hardinge mill.

For the new 8000-ton mill the following was done: grading for coarse-crushing plant 30% done; grading for power-plant and 50,000-gal. oil-tank commenced; grading done on the tram-line to the mine; and No. 2 dock and warehouse constructed. A considerable amount of other construction was accomplished at various points.

The Disseminated Copper Mines in 1915

The following table is a summary of results at the so-called porphyry mines during the past year, as compiled from the reports for 1915:

	Ore treated, tons	Copper produced, pounds	Value of copper sold	Net profits	Dividends paid	Cost, cents per pound
Chino	2,379,800	64,887,788	$11,303,956	$6,913,983	$2,609,860	7.12
Inspiration	778,851	20,445,670	*1,138,878	600,062	†1,875,000	8.13
Miami	1,348,122	41,832,059	7,262,884	3,589,681	1,681,004	8.76
Nevada	3,081,520	62,726,651	11,069,670	5,905,602	2,999,185	8.23
Ray	2,848,969	60,338,936	10,470,274	4,589,142	1,872,319	9.42
Utah	8,494,300	148,397,006	26,235,331	17,913,481	6,904,082	7.48
Total	18,931,562	398,628,110	$67,480,993	$39,511,951	$17,941,450	

*Only 6,134,355 lb. delivered. †$1.25 per share, May 1, 1916.

The percentages of recoveries were as follows:

Mine	1915	1914
Chino	66.59	67.86
Inspiration	79.95	....
Miami	75.17	69.93
Nevada	70.18	68.48
Ray	64.11	67.88
Utah	64.13	66.04

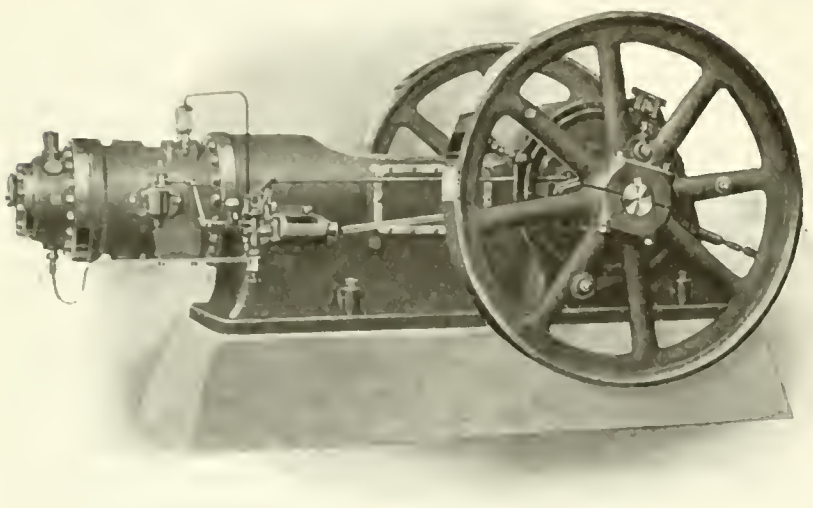
With the Inspiration now yielding nearly 10,000,000 lb. per month, the present rate of production for these properties is over 550,000,000 lb. per annum.

At the Inspiration the recovery on sulphide ore was 88.56%, now 91%, the oxide copper reducing the general average.

INDUSTRIAL NOTES

An Improved Oil-Engine

In a 44-page publication the Bessemer Gas Engine Co. of Grove City, Pennsylvania, describes the manufacture and operation of its well-known engines in detail. The company is constructing a heavy-duty type of hot-bulb or semi-Diesel engine which merits consideration. Its general design (two-cycle principle) has much in common with that of the modern automatic steam-engine. The reciprocating parts are fully enclosed and run in an oil-bath. The connecting-rod thrust is borne by a cross-head fitted with adjustable bronze shoes. The design of the crank-shaft bearings is novel, combining, as



A NEW SEMI-DIESEL TYPE ENGINE.

it does, the virtues of the four-part box with the simplicity and the rigidity of the two-piece bearing-shell. The connecting rod is of the marine type, fitted with babbitt-lined bronze shell in the crank-pin end and a solid bush at the cross-head pin.

The scavenging air does not pass through the crank-case, but is compressed in the crank-end of the cylinder instead, the latter being isolated from the crank-case by a stuffing-box, fitted with bronze-metallic packing. The inlet-valve which admits the scavenging air to the crank-end of the cylinder is of the Corliss type and double-ported. It is silent in operation and efficient, the pressure-drop through the valve-ports being less than one-half pound.

The fuel-pump is operated by an eccentric carried by a shaft-governor of the inertia type.

Water feed to the combustion-chamber is handled by a small pump also under governor control. This pump is mounted in the fuel-pump housing and driven from the fuel-pump cross-head to a short reversing lever.

The governor itself is of rather peculiar design, having been devised to meet the conditions imposed upon it by this particular class of service.

The engine will operate satisfactorily on a broad range of fuels without change of adjustment. This range includes the oils put on the market recently by many of the larger refineries and known as Diesel engine fuel-oils.

This design is conspicuous for its ruggedness and weight. Bearing dimensions are unusually large and hardened, and ground-work is used throughout on all small steel wearing-parts, opposed to phospher-bronze bushings, which are renewable.

Commercial Paragraphs

The INGERSOLL-RAND CO., of New York, has recently issued three new bulletins as follows:

Form 3036 on turbo-blowers: These are suitable for any air service where the capacity requirements range from 3000 to 35,000 cu. ft. of free air per minute, at pressures of 1 to 2½ lb. They are particularly adapted to such work as foundry-cupola blowing; atomizing oil for oil-burners; supplying blast to various kinds of heating and annealing furnaces; blowing air for water-gas generators; pneumatic conveying systems, and for ventilating purposes. Form 3029 describes the Ingersoll-Rogler Class 'ORC' Corliss steam-driven air-compressors of the familiar duplex-type, with the steam cylinders next to the frames and separated from the air-cylinders by open distance-pieces. This type of machine is offered in four different combinations of cylinders. The catalog gives sizes and capacities. Form 4120 describes the Leyner-Ingersoll water-drills, both the No. 18 and 26 types. The catalog explains the construction in detail and illustrates the different types, including numerous installation views. Copies of these bulletins are free on request to the nearest branch office.

A recent article in the trade press called attention to the fact that all the electric furnaces in Germany, operating under war conditions, were turning out 129,646 metric tons of steel every 12 months. If the SNYDER electric-steel furnaces recently sold, and those in operation today were suddenly mobilized for war service, on 24-hour basis, they would make 77,975 tons of steel a year, or within 40% as much steel as all the electric furnaces operating in Germany. These figures do not take into consideration the 12 furnaces sold in foreign countries, as well as several sold in this country which cannot be used for the smelting of steel. Europe is the originator of the electric furnace, and the steel foundry-men on the continent are considered progressive. Judging, however, from the above facts, manufacturers in this country are keenly alive to the value of the electric furnace.

Marked activity is shown in the placer mining districts of Alaska and northern California. The UNION CONSTRUCTION CO., of San Francisco, is keeping its shops working at capacity filling orders received since the first of the year. The company recently experienced the novelty of receiving a telegraphic order for a completely equipped 2½-ft. gold-dredge for George Roley, Iditarod, Alaska. Another dredge of 2½-ft. capacity and one of 3½ ft. are already under construction for the new district of Kuskokwim on Candle creek, Alaska. Four placer prospecting drills have been sent to this district. Alaska, as well as the western United States, has placed orders for fifty Neill jigs since January 1.

Seventy Lilly hoisting-engine controllers are being made for the Anaconda company at Butte. This machine is the invention of W. J. LILLY of Butte, Montana, who also manufactures it, and a booklet has been published describing the device. Briefly the controller is a governor attached to a hoist whereby it will prevent the engine 'running away' and give various warnings of danger, of importance in these times of fast haulage.

A 10-cu. ft. dredge is to be constructed for the Chicksan concession, Korea, by the NEW YORK ENGINEERING CO.

EDITORIAL

T. A. RICKARD, Editor

THE AUTHOR of the article on 'Double Roasting at East Helena' appearing in our issue of May 6 desires to apologize to the East Helena management. We are glad to assume all the responsibility ourselves, without apology. The information was given to us for publication, but not by the author. There is every reason to believe that it will do good, rather than harm, to the development of smelting practice at East Helena. Our aim is to help many and to injure none.

AS showing which way the wind of public opinion is blowing, it is worthy of note that the Northwest Mining Convention passed resolutions (1) opposing legislation calculated to disturb the good work being done by the Bureau of Mines, (2) thanking the Secretary of the Interior for expediting the issue of patents, (3) recommending changes in the Mining Law and also the appointment of a commission to revise the existing regulations, (4) asking for the establishment of an experiment station, under the Bureau of Mines, at Spokane.

TAXES in Mexico have lost their immediate interest, because nobody knows a month ahead who will collect them. The Carranza government has declared a 10% export and import tax on gold in any form and a 5% tax on silver. Another decree imposes a tax of $3, payable in Mexican gold coin, on claims covering less than 10 hectares, $6 for areas between 10 and 50 hectares, $9 for those less than 100 hectares, and $12 for over 100 hectares. These imposts went into effect on May 1, despite a protest from the American government. However, the biggest tax paid by those mining in Mexico is the uncertainty as to which moment will be their next.

AMERICAN participation in the exploitation of Africa includes the concessions in the Congo region secured nearly ten years ago by the Guggenheims from the late King Leopold of Belgium. Among the larger stockholders are Messrs. Thomas F. Ryan, B. M. Baruch, and A. C. Beatty, the last having conducted the negotiations that preceded the business. About $2,000,000 has been spent on these African concessions and various mineral deposits have been uncovered, the most productive so far being diamonds, although gold, rubber, and ivory are mentioned as sources of future revenue.

TUNGSTEN is a metal much in demand, and the prospecting and mining of it are attracting attention in various parts of the West. In this issue, under the Review of Mining, we publish letters from Ely, Nevada, and Fairbanks, Alaska, both recording the beginning of new tungsten mines. At the former place, quartz veins that were prospected in earlier days for gold and silver have been found to contain scheelite and hübnerite. In the Alaskan region, prospectors traced scheelite 'float' to the veins that were its source, and have found this tungstate of lime in gold-bearing quartz, in a manner resembling the veins at Grass Valley described in our issue of January 8.

METHODS of stoping by branched raises are discussed in this issue by Mr. F. W. Sperr, Professor of Mining in the Michigan College of Mines. This relatively new system of underground excavation is interesting because of its simplicity and because of its recent adoption in modified forms at several important Western mines. The Nevada Consolidated Copper Co. is using a system of branched raises at its new Ruth mine near Ely, in conjunction with the well-known Ray method of caving. We shall have more to say of the underground conditions at the Ruth mine in a later issue. Professor Sperr's article will be found of interest because he writes from the point of view of a Lake Superior engineer that has visited many of the Western districts. Several of the present methods of stoping, more particularly in wide orebodies, were worked out in the Lake Superior region, and were then adapted and modified in the West.

DISCUSSION this week covers six pages. We are glad to extend this department of the paper, for the subjects discussed are those of immediate interest to our readers and we like them to have their say on matters that concern them most. The first letter furnishes some short-cuts to the estimation of tonnage in a flotation mill; it is contributed by Mr. C. Eustace Dwyer, foreman of one of the Federal Mining Co.'s mills in the Coeur d'Alene. The next contribution discusses sundry peculiar features of the Republic ore deposits, arguing that these are the end-products of magmatic differentiation. Mr. A. M. Balfour is a mining engineer resident in the district and thoroughly familiar with local geologic conditions. The Foster bill for amending the mining law was criticized recently by us, and we are glad now to print an expression of opinion from one of the men most directly affected by the proposed alteration. Mr. George E. McClelland speaks for the prospector. Another subject of general interest just now is the Patent Law, concerning which we have published several communications. Mr. William E. Greenawalt, who gives us his views this week, is a metallurgical engineer who can write feelingly on the subject, for he is many times an inventor himself. His opinions are at variance with

those previously published by us and that makes them all the more welcome. Most miners are familiar with the tellurides of the precious metals, but their sister compounds the selenides are more rare. Mr. Walter W. Bradley, of the California Mining Bureau, gives some valuable notes concerning the detection of silver and gold in combination with selenium. Finally, we publish a most useful criticism of Arizonan practice in drill-sharpening contributed by Mr. Lucien Eaton, superintendent of an important group of iron mines belonging to the Cleveland-Cliffs Iron Company in the 'hard-ore' district of Michigan.

HIGH FINANCE has found an interesting exponent in Mr. Otto H. Kahn, of the banking firm of Kuhn, Loeb & Co., New York. He insists that "finance does not mean speculation" nor "fleecing the public, nor fattening parasitically off industry." He also gives us a new definition of a 'financier,' who is one that "has some recognized relation and responsibility toward the larger monetary affairs of the public." That is well; and on those rare occasions when that relation becomes not only parasitic but piratic, let us call him not a financier but a grand larcenist. Mr. Kahn confesses grudgingly that "high finance has in some instances strayed from the highest standard" and "there have been some occurrences which every right-thinking man must deplore." Deploring is not enough; let the "right-thinking man," such as Mr. Kahn, refuse to do business with predatory speculators. The brutal fact is that business makes strange bed-fellows; the man who can make money, and keep out of jail, can find partners in the highest circles of finance.

WE have received a copy of a pamphlet on the 'Origin and Distribution of Ore in the Coeur d'Alene' by Mr. Oscar H. Hershey. To tell the truth, we had a chance to publish this essay in our columns and would have been happy to do so but for the fact that it was too long and could not be abbreviated without being spoiled. To those who are interested in the geology of that important mining region of Idaho, this pamphlet will appeal as a careful and lucid presentation of the evidence bearing upon the origin and distribution of the silver, lead, copper, and zinc ores, now the subject of successful mining on a large scale. Mr. Hershey marshalls his own observations and gives courteous attention to those collected by others, notably the gentlemen of the U. S. Geological Survey. He divides the veins into systems based on geologic age; he notes the mineral combinations characteristic of these vein-systems; and then he tests the theory of a zonal arrangement with relation to the intruded granite. This hypothesis he attacks vigorously, and in lieu of it he suggests a diffused mineralization in one particular terrain as the source of nearly all the lead and zinc in the ore deposits of the Coeur d'Alene. In short, he challenges the magmatic theory advocated by Mr. F. L. Ransome and other gentlemen of the Survey. In this tilt, he has our hearty sympathy, for we have the best of goodwill for the work of the energetic mining engineers who have pioneered the geologic study of so many of our Western mining regions, making investigations and collecting observations that have been more useful to actual mining and more helpful even to the Survey than the ungracious acknowledgment of some of its officers would permit one to infer. Mr. Hershey has devoted a great deal of conscientious study to the Coeur d'Alene. In behalf of the mining public, especially on the Pacific Coast, we tender our friendly appreciation.

GASOLINE is a product in such general use that the price of it is a matter of concern to the major part of the community. Hence a discussion of the conditions contributory to the high cost now prevailing is timely. We are indebted to a contributor, as modest as he is well informed, for an article on the subject. His argument is summarized by two graphic diagrams, one contrasting production with the number of automobiles in use and the other exhibiting the relation between the yield from the Cushing well and the price of crude oil in the state of Oklahoma. He emphasizes the expansion in the use of the internal-combustion engine as the chief factor in the rise of gasoline and suggests that relief for the consumer will come through such processes of fractional distillation as have been developed already by Messrs. Burton and Rittman, whereby an increased yield of gasoline is obtained from crude oil. It is noteworthy that the ratio of gasoline production to crude-oil production increased from 6.9% in January 1915 to 9.2% in December of that year. It is estimated that the number of automobiles in use in this country will increase during the current year from 2,000,000 at the beginning of the year to 3,000,000 at the end. It is also noteworthy that the Federal Trades Commission has ascertained that the Standard Oil Company's price for gasoline was 4% below that charged by 47 other refineries, so that the idea of a monopolistic conspiracy does not seem warranted. A good deal of loose talk is prevalent on the subject of oil production. Prominent people at Washington are calculating that if the present rate of output is maintained we shall find our reserves of oil exhausted in 23, 27, or some other specific term of years. A Californian authority, in a Senate document, closes a valuable summary of statistical information with the threat of a speedy exhaustion of our oil-supply and indulges in a rhetorical climax in which we are given a vision of the day when "our battleships will swing helplessly at anchor, and our country will resound to the martial tread of a triumphant foe." This we consider without sufficient warrant of fact. Substitutes for gasoline are bound to be found as the 'cracking' process is developed; indeed, the making of benzol from coal is already furnishing an alternative fuel for the motor-engine. Our resources in oil-shale—in Wyoming, Colorado, and Utah—have hardly been touched. But in deprecating exaggeration concerning the exhaustion of our oil supplies, we do not minimize the stupidity of burning crude oil as fuel, and thereby wasting so many of the more valuable by-products, as is done at the wells themselves.

Aids to Success

In recent issues our readers have joined with us in discussing the essentials of mining education and the qualifications of a successful mining engineer. An honored contributor, himself formerly professor in a well-known School of Mines, writes to say: "Somehow or other the successful engineer lacks in many instances the qualifications that recent writers consider so essential. You know a lot of these men: why not study them and give us some cold-blooded deductions—not what you would like to find, but what you actually do find." That is a challenge to which we respond herewith. So we start by saying that apparently the first requisite is good health. Undoubtedly a man's physical strength and activity, as ordinarily understood, are factors in his exacting work as a mining engineer, not only in youth when he is a junior member of the staff in mine or mill but in the riper years when he has to travel to the waste places of the earth and expose himself to the rigors of inclement climates or the miasmas of the jungle. That is why we tell our young friends not to go to malarial countries, risking an infection that is so hard to eradicate. Sell not your birth-right for a mess of pottage. Physical unhealthiness is a cause of mental unfitness. A man's temper, even his temperament, in large measure, is the reflex of his bodily condition. Joyous good health not only promotes clear thinking but makes men attractive to their fellows. It is true, poor health did not deter some great men, like Darwin and Huxley, from splendid intellectual achievement, but the average man succumbs under conditions so unkind. Lacking the stamina for sustained effort, he is unable to apply himself with assiduity to his work, so that his contemporaries pass him in the great competition. Therefore we choose good health as the first gift to the fortunate. Next, we reckon a good start: the favors of kindly circumstance, such as a father able to pay for the necessary education, a kind uncle to give the graduate a job, and friends glad to give a push when most needed. Of course, there are a few—a very few—who have succeeded despite the lack of all such aids; they picked up their education as best they could, from books, at night-school, from chance acquaintances; they started by doing manual labor; they won grudging promotion by their merit, and owed little to patronage until they had placed a firm foot on the ladder of success. Such men are the finer and stronger for the struggle from which they emerged victorious, but even as regards some of these we think the world has lost by not giving them the best of education and training, at the start, and thereby developing to their highest the exceptional powers and peculiar aptitudes now manifest. So, next to good health, we put 'push' and 'pull.' Those are the words, as we have said before, written on the opposite sides of the door that opens the way to a successful career. Next in importance we put the knowledge of men, the ability to diagnose human motives, the instinct to say and do the right thing, the psychologic intuition that enables a man to guess which way the cat is going to jump. This quality is one that may become cultivated in the course of experience; it will make a man helpful, sympathetic, and loyal, or, by the perversity of nature, it may be used by him to humor, thwart, and deceive his fellows. Looking around us, we see men who have become successful and honored by the proof of good faith and loyalty to their associates and employers, but we also see men who have become rich and powerful by lack of scruple and a selfishness that disregarded honorable obligation. In life, as in poker, the bluff sometimes succeeds; even the four-flush may take the pot from a moderately good hand. Self-assurance may cover many defects of training and knowledge. You can fool most of the people for a considerable period of time. Given equal ability, the confident man is likely to out-distance the modest one. Confidence is strength.

Next, we mention perseverance. Here we are in close agreement with the Sunday-school teacher. Persistence of effort and tenacity of purpose are forces that accomplish wonders. To 'make up your mind' to master a given branch of technology and so become a leading specialist is not, however, the same thing as dreaming of getting there or ruminating on the pleasure of having got there. Many men we know owe a great deal to an innate obstinacy that enabled them, through thick and thin, through smooth and rough, to "keep their eye on the ball." This fixity of purpose or stability of mind is what constitutes character, as distinguished from the want of it. "Weak as water" and " a cake not turned" are the type of Ethelred the Unready. Such are not born to success. Tenacity of will, even in men not greatly gifted, will suffice to take them far on the road to achievement. So we put the chief factors of success in the following order: good health, the favor of circumstance, knowledge of men, perseverance. To these we might add, as a factor peculiarly conducive to pre-eminence under the conditions of modern industrial effort, the power of organization and the executive ability that usually goes with it, so tremendously in demand wherever complex and far-reaching technical operations are being conducted with the aid of much capital and more men. Of course, in all of this we have assumed some measure of mental endowment: in other words, a moderately clever young man. There always will be inequalities of brain-power, despite the declarations of perfervid rhetoricians; some men scarcely know their right hand from their left; others can orient themselves at a moment's notice; witless will serve his master to the crack of doom; but in estimating the factors of success we must assume—and we have assumed—at least an average proportion of ability. And we conclude that the handicap of differences of ability at the start is more than overcome in the long race that begins in youth and ends in old age. There remains only the definition of "success." We have had to give the word its conventional significance, which is that of a prosperous conclusion or an advantageous result. Some men not deemed "successful" in the common meaning of the word are happy in having got what they wanted; others lab-

clad "successful" have found that the cool waters beckoning them were only a sandy waste. "Success" may be a rainbow or a mirage. To most men the chase is better than the kill, the striving is finer than the achievement; in any event, it is certain that no man can be happy who is not his own philosopher.

United States Smelting

We referred the other day to the fine showing made by the American Smelting & Refining Company in its annual report. It appears that its chief competitor, the United States Smelting, Refining & Mining Company also did well last year. Some details concerning this important enterprise will interest our readers. The company was organized in 1906—just ten years ago—as a holding corporation for enterprises of the character indicated by its name. It owed its origin to that energetic individual, the late Albert F. Holden, backed by a group of capable Boston men, notably Messrs. William G. Sharp, W. H. Coolidge, and B. Preston Clark, also the late Robert D. Evans. The technical staff includes Messrs. Frederick Lyon, Sidney J. Jennings, A. P. Anderson, George W. Heintz, and Carlos W. Van Law. The operations in which the company engages, through its subsidiary organizations, are of a most diversified character, industrially and geographically. Among the mining properties the most interesting just now is the Real del Monte at Pachuca, where, despite Mexican misrule, the work of underground exploration was rewarded a few months ago by the discovery of a large tonnage of rich silver ore on the 1400-foot level. This property includes 180 mining claims, covering 4270 acres, besides 26,000 acres of agricultural land—evidently a magnificent estate. During 1915 an output of 390,000 tons was made, the average content being 13.9 ounces of silver and $1.48 in gold per ton, exploited at an average total cost of $4.16 per ton. The output of silver, namely, 5,321,000 ounces, is being exceeded this year, being at the rate of 700,000 ounces monthly. The deepest workings are at 2050 feet and one of the difficulties of operation is the expense of pumping. However, this Mexican venture gives promise of being an increasingly productive enterprise. In Utah the company controls the Centennial-Eureka and Bullion-Beck mines in the Tintic district, and the Telegraph, Niagara, and other mines in the Bingham district. In Nevada it controls the old Richmond and Eureka properties, now consolidated, but awaiting the rebuilding of the branch railway before resuming operations on an adequate scale. In Arizona the company owns the Gold Road mine, at Oatman; this has proved a poor purchase, the ore decreasing in richness on the lower levels, but the mine is yielding a small profit pending further exploration in depth. The Tennessee mine, at Chloride, in the same region, is being operated productively under lease and bond. In Shasta county, California, the company controls the important Mammoth mines, besides several promising groups of claims in the vicinity. Last year the production was 251,907 tons of ore averaging 1% copper and $2 per ton in the precious metals. In addition 11,766 tons of zinc ore was produced.

Among the company's metallurgical operations are the Mammoth copper smelter, with a capacity of 450,000 tons of charge per annum. This establishment also treats custom ores from mines in California, Nevada, and Oregon. At Needles, on the Colorado river, the company has a concentrating mill that treats the output of the Tennessee mine and custom ore from other mines across the river in Arizona. In Utah the important lead smelter at Midvale belongs to the United States Smelting Company, which also operates a lead-zinc concentrator in the same locality. The smelter has a capacity of 481,800 tons of charge per annum, while the concentrator has about half that capacity. Both are designed on the most modern lines. The company also owns zinc smelters at Altoona, Iola, and La Harpe, all in Kansas. These have had the advantage of the increased production of zinc ores and the rising price of spelter. The three zinc plants have an aggregate capacity of 91,000 tons of ore per annum; they use gas for fuel and are equipped for extracting the precious metals. Recently the company has taken a lease on the Ravenswood mine in Missouri and has erected a mill of 218,000 tons yearly capacity to treat the zinc ore produced. The company controls a copper smelter and an electrolytic copper refinery at Chrome, New Jersey. The latter has a capacity of 180 million pounds of copper, while the smelter can treat 200,000 tons of charge per annum. Ores, mattes, and other products are received from Canada, Spain, Cuba, and South America, besides the company's own mines in this country. Finally, at East Chicago, the company owns the Grasselli lead-refining plant, which has an annual capacity of 72 million pounds of lead. In these two refineries the company holds only an equal interest with Aron Hirsch & Sohn of Halberstadt, Germany.

On turning to the annual report we find that these multifarious energies made a turn-over, last year, of

	Total	Value	Average price
Copper	26,923,674 lb.	$4,894,723	18.18c.
Lead	87,102,179 "	3,954,438	4.54
Zinc	34,105,471 "	5,102,178	14.96
Silver	12,071,963 oz.	6,031,017	49.96
Gold	196,481 "	4,061,262	$20.67

The total earnings were $7,579,184, out of which a profit of $6,592,324 is declared. From this a 7% dividend was paid on 486,350 preferred shares of $50 each and 75 cents per share on 351,115 common shares of $50 each. The total capitalization is $75,000,000, half in preferred and half in common stock. At the beginning of this year the company organized a metal-selling agency of its own, emphasizing its status in the business of mining and smelting. The past year was one of expanding prosperity, the gross and net earnings alike being the highest in the company's history. As far as the miner is concerned, it is a good thing to have competition in the smelting business and we are glad therefore to see this company prosper.

DISCUSSION

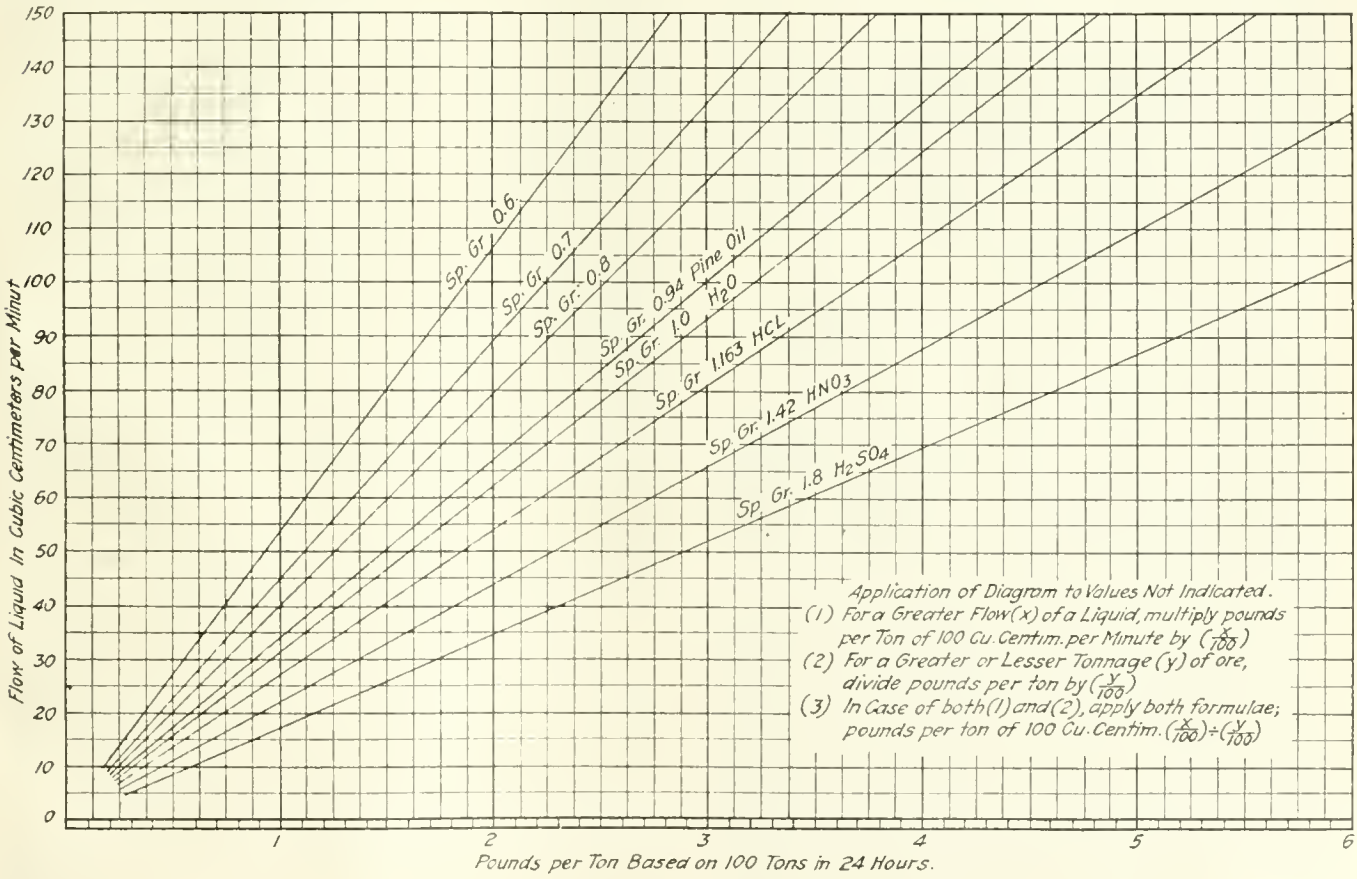
Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Tonnage Formulas

The Editor:

Sir—Having noticed Mr. John Allingham's formula for estimating slime tonnage, I am submitting a chart that flotation men may be glad to use in estimating the consumption of oils and acids in their plants per ton of feed.

For my copy of the chart I am indebted to Mr. O. B. Hofstrand, who prepared it for his own use and in a fitting size for the Lefax books.*



A concrete example showing how to use the table may not be amiss: Assume that a plant treats 450 tons per 24 hours and that the consumption of pine-oil is 160 cc. per min.. it is desired to find the consumption of pine-oil in pounds per ton of feed.

From the point of intersection of the 100 cc. per min. line and the pine-oil line, follow down and read the figure 2.95. which would be the consumption in pounds per ton at 100 cc. per min. and 100 tons of feed per 24 hours.

Inasmuch as the consumption of oil is greater than 100 cc. per min. and the tonnage treated is greater than 100 tons per 24 hours, we must use the third formula to arrive at our final figure.

Thus: $\frac{2.95 \times \frac{160}{100}}{\frac{450}{100}}$ or $2.95 \times \frac{160}{100} \times \frac{100}{450} = 1.05$ lb. per ton.

Doubtless many mill-foremen and superintendents desire to estimate the tonnage of feed to some particular unit in their mill without going to the trouble of much sampling. I will give a method of calculation used extensively in the Coeur d'Alene, but which I have never seen printed.

For the application of this method the tonnage of either the concentrate or the tailing produced must be known and also the assay of all three—heads, tailing, and concentrate. The basis of the method is the efficiency by assay of the plant.

*[We have combined the two charts in one.—Editor.]

A concrete example, used in figuring the tonnage to a certain flotation plant, in which both a lead and a zinc concentrate were made, will be clearer than the use of formulæ and 'unknowns.'

The concentrate tonnage is known and also the assay (in zinc) of the heads, tailing, and concentrate.

Products	Assay Zn%	Symbol
Feed	5.7	H
Tailing	2.6	T
Concentrate	10.4	C

Then:

$$\text{Ratio of concentration} = \frac{C-T}{H-T} = \frac{40.4-2.6}{5.7-2.6} = 12.1$$

$$\text{Effieiency of concentration} = \frac{C \times 100}{H \times R} = \frac{10.4 \times 100}{5.7 \times 12.1}$$

58.7%.

Made 211 tons concentrate of 40.4% Zn, which equals 85.2 tons of metallic zinc.

85.2 tons equals 58.7% of the zinc in the original feed.

100% − 58.7% = 41.3% zinc lost in the lead concentrate and tailing, or 59.9 tons metallic zinc.

85.2 + 59.9 = 145.1 tons of metallic zinc in the original feed.

$\frac{145.1}{0.057} = 2545.5$ tons of feed to the plant.

The tonnage of concentrate or tailing could, by knowing the feed tonnage, be equally well calculated by this method.

C. Eustace Dwyer.

Superior, Mont., April 14.

Some Peculiar Ore Deposits

The Editor:

Sir—Two years ago, in a paper read before a local meeting of the A. I. M. E., I ventured the opinion that the ore deposits of Republic (Washington) were themselves magmatic injections, the magma being the residuum, or mother-liquor, resulting from the differentiation processes of long-continued vulcanism.

At that time I was operating a lease on the upper levels of the Lone Pine mine. Not long after commencing work it became evident that something was wrong with the sampling method. Close inspection of the working-faces, coupled with occasional visits to neighboring properties, revealed a curious condition, and one that I had never before encountered. The 'black sulphides'—to use the local term—resemble the color of fountain-pen ink on clean white blotting-paper, appeared to have been distributed through the quartz by means of an atomizer, and again as if a passage for their reception had been prepared by a huge corkscrew. In casting about for an explanation, it seemed perfectly natural to associate the curvilinear habit of the sulphide distribution with the phenomena accompanying convection currents in a liquid. In this connection it may be well to state that the above remarks apply to ore of medium grade. The rich ore, carrying native gold, selenide of silver, and telluride of these metals, was usually found close to the hanging wall, and occasionally filling small fissures and fractures running away from the main deposit. These high-grade streaks were of a peculiar striped appearance, resembling nothing so much as a series of closely crinkled lines drawn parallel to one another, with a fine pen, on a sheet of white blotting-paper, the dispersion of the ink through the fabric of the paper being in faithful accord with the actual appearance of the sulphides in the rock. Under a strong lens, a slab of pure white quartz taken from the Republic mine looked for all the world as if some vandal had blown a minute quantity of lampblack over the surface of a bowl of milk. Competent authority has declared the black sulphides to have a composition approaching that of tetrahedrite.

It is when one comes to speculate upon the cause of the fissuring in the andesite that trouble and doubt sit at his elbow. That the fissures were open when occupied by the invading magma there seems no reason to doubt; that the magma itself supplied the force needed to rupture the rocks is open to question. In more than one of the mines open to inspection there are small side veins and pockets filled with a cloudy compact quartz, the presence of which it is hard indeed to explain except by the invasion of a mud-filled receptacle by a viscous magma. The quartz of these occurrences is generally barren. In appearance it is of a muddy tint, with distinct wavy lines of all shades of gray and black, of a pattern that is reminiscent of the ropy material sometimes observable on the selvage of a lava flow.

Nor is the Republic district the only locality where the magmatic injection theory seems to offer the most rational explanation of the origin of quartz veins. In the Cabinet mountains of Montana, among the flat-lying quartzites and slates, there are quartz veins that appear to have invaded these rocks under pressure sufficient to produce marked doming of the overburden. These are veritable laccoliths in miniature, and so far as I am aware, there are no eruptives within many miles of the locality. These deposits are barren and of small size, if surface indications are to be relied upon.

An interesting feature of that region, and one that may lend an odd twist to the problem with which the already overworked mental capacity of the prospector is beset, is that several of the veins in the slate contain gold, zinc, and in one instance, hübnerite, and in another scheelite; the tungsten minerals, so I am informed, being closely associated with the blende and galena.

From the Missoula River side of the district, eight years ago, a prospector found some material in his gold pan that refused to separate from the gold. He preserved the pannings in a bottle, and the following winter he came to me at Great Falls with the request that I 'put him wise.' I was unable to enlighten him, but suggested that he send his 'damfunnystuff' to a qualified analyst. He did. Four years ago I met one of his partners, who told me that the contents of the bottle contained "some dam thing or another that was used in making some new-fangled light." I tried him with thorium and all the 'ites and 'iums I had with me, but

in vain; he had forgotten. It may have been monazite.

What of the thermal conditions required to deposit those minerals? Is the lead and zinc content of these veins to be explained by stating that these minerals are themselves the end product of some mysterious differentiation process? For instance: a series of transformations resulting from the decomposition—or molecular decay—through loss by emanation of radio-active minerals of higher atomic weight.

We prospectors are having a hard time indeed; there's that other beast of prey, the plumbojarosinoceros, but Nevada will go dry some day.

A. M. Balfour.

Republic, Washington, April 25.

Mining Law Revision

The Editor:

Sir—I have read the text of the bill introduced before Congress by Representative Foster of Illinois. As one of those whose interests would be directly affected by the passage of this bill, I beg to offer some comment:

The new law is not to apply to locations already made at the time the proposed changes go into effect. The old right of apex in simple form and fact remains. The questions of faulting and junctions will be still with us. The fact of being the discoverer is no longer pertinent.

The writer of the proposed law probably was never five miles from the nearest scrub pine about to mark a claim with no rocks in sight within a half-mile or more. This is a condition that arises occasionally in a porphyritic country of flat nature. Why not a mound of brush and dirt and a rock or two on top to hold a tobacco-tin with the mark inside away from grasshoppers, lizards, rats, chipmunks, and weather? In marking lines, why not specify the manner of marking to be such as can be most easily done with consideration to the greatest effect. Nobody wants to be over-lapped. The Oriental claim south of Goldfield was plowed around fully 25 years ago and is still very easily traced. That is dry country. On the Mother Lode such a method would be no good.

Proof of failure to find a probably remunerative vein or lode must be given by anyone trying to dislodge the locator and holder. It is the same old story with a new chance to do some hazy proving. A locator finds a vein. He looks at it and says it is fine. He doesn't have to test it to see. He has obtained enough pannings in some spot out of line of the strike of his vein and decides to make the vein of ore hit both places. He lays off his claim and maybe gets nearly 3000 ft. of the best outcrop within his lines. What about it? How is a prospector to make a claim with straight lines follow a crooked vein? I exposed a vein by work done that had been patented and mapped as running from the location post at one end to the centre end at the other. It really took a turn and went across the side-line at an angle of 60° and hadn't even been faulted till it was well outside the claim. Too much supposition in this case, too. Rarely can a man keep from being bothered by other locators if he thinks he has anything good. He will probably have to mark it before he knows what he wants. This section will be abused. It will be unsatisfactory. Too much evidence has to be dug up against a locator for it to be worth much. If used rightly it is valuable and an improvement. It presumes that a locator has no other interest on earth save digging on his claim. It is a little tight in its specifications; it will promote fraud.

Extra-lateral work cannot be carried on under a claim alongside a lot of low-grade veins because it takes too long to get that far along. There is the time limit. What if the alongside claim should be kept up only long enough to bring the time limit into operation against the locator of the valuable vein and then should get into the hands of a grafter by new location or transfer?

Can a locator or possessor of locations abandon any location in case he wants to change to his advantage—to allow him to take up something that later looks better?

The tunnel-site claim is a clean-cut improvement, but it doesn't allow for immunity of trespass at the mouth of the tunnel or mode of approach across surface. Nowhere have I seen provision for enforcing permission to pass across other property to reach a property beyond. I know of no legal way to enforce permission of access by a practicable route. What about prospectors and owners of locations being called upon through the County Clerk's office to furnish direct statement of the time or times when assessment work was done on claims?

George E. McClelland.

San Francisco, May 2.

Patents and the Patent Office

The Editor:

Sir—There seems to be a great deal of misconception as to the nature of patents and the operation of patent laws. A patent, *per se*, has no value, unless the subject-matter patented has value. The Patent Office cannot inject value into a patent.

Complaint is frequently made of the great number of worthless patents issued by the Patent Office. If a patent is worthless, and the patentee is satisfied to pay the fee, the patent attorney satisfied to receive it, and the Patent Office is enriched thereby, why should there be any cause for complaint? If the patent is contested, that of itself is evidence that it has some merit, and that the patentee is entitled to consideration. Inventions are no different from other efforts, and patents should not be different from other forms of property. Only a small fraction of all human effort results in phenomenal success, a larger portion in mediocrity, and almost all in failure or indifference. Patents are no exception to this general rule.

A patent granted on a trivial improvement is quite harmless. Any patent, based on an improvement evident to any mechanic, as frequently charged, can easily be surmounted by a mechanic of equal ability; if it cannot,

that indicates that the improvement is not trivial, but forms the basis of a valuable patent. Because a patent does not represent a basic idea or a great advance in the art, is no reason why it should not be granted. A small improvement is entitled to as much consideration as a great improvement, for precisely the same reason that a peanut vendor is entitled to the same protection in his business as the business corporations usually classified as 'trusts.' Similarly, an applicant for patent who may be ignorant in the art he is working is entitled to the same consideration as the most highly educated applicant. The fact that Carrie Everson was not a specialist in metallurgy cannot, of itself, detract from the value of her invention.

Much of the criticism of the Patent Office is unfounded. The cause for the criticism lies deeper than incompetency in the Patent Office staff. The granting of a patent is not so much a matter of research as opinion based on that research. In all cases of reasonable doubt there is less harm done by granting a patent than in refusing it. Let it be remembered that the Patent Office staff has the same difficulties to contend with as a court, and there is no unanimity in court decisions, even based on exhaustive evidence.

No action of the Patent Office, under any system, can, or should be final, until the highest court of jurisdiction has passed upon it. There is absolutely no practicable way in which an unassailable patent can, with justice be granted. The present patent law, on the whole is excellent. What is most urgently needed is a technical court to preside over patent cases, and the method of procedure should be greatly simplified and expedited. In any event, there should not be more than one appeal.

Much has been said in commendation of the German patent laws. Quite as much, if not more, injustice results from the German patent laws as under the American laws. Under the German system, any applicant can be forced into litigation before the patent is granted, and this is frequently done by strong financial interests to eliminate weaker competitors. A foreigner, under German laws, has not got the same fair chance as he has under the American patent laws.

Every patent looks simple after its simplicity has been pointed out; it is usually self-evident after it is made so. On the whole, the present examinations are strict enough —stricter a thousand times than the conditions governing the aquisition of material property from the Government. When an application is filed for a patent, all the records of the U. S., British, and German patent-offices are ransacked to see that the applicant does not get anything that does not belong to him; even if a U. S. patent, taken in connection with a British or German patent, shows anticipation, the patent is not granted. If a patent is granted, the applicant can enjoy a questionable right for 17 years. If a man files a claim on mineral land, even though it has been discovered a thousand times and abandoned, and even though the U. S. Geological Survey has mapped it out as mineral land, he is still entitled to 'discovery' and valid location, and can obtain title forever. Why then quibble about the unjust rights of inventors?

The trouble in the patent law is not so much a matter of the system of granting patents, or in the Patent Office staff, as in the proper adjustment of what each respective inventor is entitled to, under the conditions. There is nothing so new but that it contains something that is old, and there is nothing so old but that it may contain something new. No inventor yet ever produced anything out of a clear sky. On the other hand, it is safe to say that there are few patents indeed, that do not contain some element of novelty, small though it be. In the last analysis the worth and validity of a patent can only be interpreted in the light of the prior state of the art, and in this interpretation pioneer patents, whether expired or unexpired, should be given the benefit of every doubt. No prior patent can or should be limited by a later patent on the basis of specific use or definite proportions. If this were done every pioneer patent could be invalidated by numerous later patents claiming enough specific uses and a great variety of proportions, and if one such patent is valid, all should be valid, and the pioneer patent would be hedged in on all sides.

No fault should be found with unworked or unexploited patents. After an applicant gets a patent it should be his to do with as he pleases, just the same as a patentee of a mining claim can, according to the present laws, let it lie dormant forever. It may be all wrong that this should be so, but it would be an outrage on patentees to require a patent to be worked, so long as other forms of property are not subjected to the same restrictions.

Patents are usually regarded as monopolistic. Clearly this is a misconception and a misnomer. Nothing could be further from the truth. Patents may be made the basis of a monopoly, but there is not a single monopolistic element in the patent laws. A patent indicates ownership, the same as that of a railroad or a mining claim. Neither of these constitutes what may be regarded as a monopoly. Because a man has a mining claim which belongs to him and his heirs forever, does not prevent anyone from locating an adjoining claim, neither does a patent prevent anyone else from accomplishing the same results in another way. It is only when enough mining claims are acquired or controlled to manipulate prices and output of the material mined, either by an actual or implied agreement, that it becomes a monopoly. The only way patents can become monopolistic is by a similar procedure. Morse transmitted intelligence by telegraph, but that did not prevent Bell from doing the same thing by telephone, nor Marconi from doing it by wireless. Neither of these, taken by itself, can be regarded as a monopoly, but if the important patents were controlled by one interest, either actual or implied, it might be regarded as a monopoly, differing in no way from other monopolies or so-called trusts, and would have nothing to do with the patent laws.

Then, too, all patents expire at the end of 17 years. Is

this socialistic or monopolistic? What a wail would be heard if mining claims, for example—which, to say the least, have no better rights to perpetual ownership than a patent right—were to be placed under the same laws as the patent laws, which so many delight in calling monopolistic? The fact is that all intellectual property is governed by extremely socialistic laws, while material property is governed by extremely monopolistic laws. A patent, which is one form of intellectual property, should be given every fair consideration, interpreted in the light of the prior state of the art and claims of respective patentees in that art.

W. E. Greenawalt.

Denver, April 15.

Selenide of Silver

The Editor:

Sir—In a recent search through available literature on the subject of selenides, I was unable to find any mention of such at the De Lamar mine in Owyhee county, Idaho. Hence, it may be of interest to know that the writer identified a silver selenide in one of the veins in that mine about five years ago. During the latter part of 1910, we had a disagreement over bullion settlement with the American Smelting & Refining Co.'s Omaha plant. In the course of the correspondence resulting, E. V. Orford, manager of the De Lamar Co., was informed that the smelter's chemist had noted the presence of selenium in the bullion, from the reddish fume arising when the bars were re-melted for sampling. (Incidentally it may be remarked that subsequent investigation finally proved that the cause of the disagreement was not the selenium, as at first thought, but an impure 'proof' gold, which we were using in our bullion-assays.) I made numerous tests, from that time forward for several months, before I was able finally and definitely to ascertain the particular part of the mine from which at least a portion of the selenium was coming. The cyanide precipitate always gave a strong test for selenium, and once or twice I obtained a good reaction for tellurium also.

In April 1911, in a sample from the '77' vein, on the 9th level, west stope, in a white "lamellar"[1] quartz (pseudomorphic after calcite), I noted small streaks of a dull-black mineral which before the blowpipe gave the strong red fume and radish odor of selenium, and an easily reduced silver bead. As it was closely associated with the silver sulphide, argentite (Ag_2S), the mineral[2] may be aguilarite, $Ag_2S + Ag_2(S,Se)$, though I have not yet made other than qualitative tests on it. Pressure of other work has prevented my making any quantitative determinations on the material, samples of which I still retain, hoping that some day I may find opportunity to investigate it further.

The occurrence of selenium recorded by Lindgren and Bancroft[3] in the Republic district, Washington, is intimately associated with tetrahedrite, but I do not recall obtaining a reaction for copper in the De Lamar material. J. E. Clennell[4] mentions "a small quantity of copper" in the bullion of the Redjang Lebong mine in Sumatra, in connection with the occurrence of silver selenide there. Spurr,[5] describing the presence of selenium at Tonopah, Nevada, says it is found "in part, at least as a silver selenide." He[6] likens the Tonopah ore deposits to those of the Silver City-De Lamar district; also[7] likens the De Lamar deposits to those of Waihi, New Zealand, as does Lindgren,[8] but neither of them mentions selenium or tellurium at De Lamar. Lindgren, in listing the vein-minerals of the Silver City-De Lamar district, does not speak of any selenide in that area nor of any copper mineral in the De Lamar mine. Pyrargyrite and miargyrite are recorded, but no tetrahedrite. Gold is described as also being associated with the selenium of the Republic veins.[9] The De Lamar bullion was low in gold, assaying 40 to 90 fine in that metal, and up to 900 fine in silver.

Drill-Steel Sharpening

The Editor:

Sir—I have read with interest Mr. P. G. Beckett's article on 'Drill-Steel Sharpening at the Old Dominion Mine' in your issue of April 22. With a few exceptions the practice at the Old Dominion follows closely the standard Lake Superior practice of two or three years ago. The greatest variations from present practice are in the large difference in gauge for successive lengths of steel and the welding of 'Rocky-mountain' steel on round shanks. It is evident that the ground at the Old Dominion mine is not hard on the gauge, otherwise it would be impossible to standardize on two-foot changes; and it is probable that more careful forming of the bits would make it possible to reduce the changes in gauge to $\frac{1}{8}$ in. and possibly $\frac{1}{16}$ instead of $\frac{1}{4}$ inch. The advantage to be gained by such a change is obvious. Assuming that the gauge of the longest length of Leyner steel remains at $1\frac{3}{4}$, changes of $\frac{1}{8}$ would make the starter $2\frac{1}{8}$ diameter, instead of $2\frac{1}{2}$, with a cutting-area only 70% that of the starter at present used. If $\frac{1}{16}$ changes are used the starter would be $1\frac{15}{16}$ diameter, and the cutting-area would be little over 50% of that of the $2\frac{1}{2}$-in. starter. As a matter of fact the reduction in cutting-area, with its consequent increase in drilling-speed, would be greater than I have indicated, for the gauge of the long drill could be reduced to $1\frac{5}{8}$ and still give plenty of room for $1\frac{1}{2}$-in. powder.

I do not wish Mr. Beckett to consider my remarks as

[9]Lindgren and Bancroft, *loc. cit.*

adverse criticism of the practice at the Old Dominion mine, as I am not thoroughly enough acquainted with conditions there to pass judgment. I feel confident however, that as much can be done in reducing gauge intervals there as has been done already in the iron and copper districts of Lake Superior. In the Copper Country, Mr. C. D. Lawton, of the Quincy Mining Co., and Messrs. M. M. Morrison and Ocha Potter, of the Calumet & Hecla Mining Co., have perfected their drill design and drill sharpening practice to such a degree that they standardize on $\frac{1}{16}$ changes in gauge for 2-ft. changes in length.

At the Cliffs Shaft mine at Ishpeming, the largest hard-ore mine operating on the Marquette range, I have made it standard practice to use a $\frac{1}{16}$ change in gauge for foot changes in length, the gauge of an 8-ft. drill being $1\frac{1}{2}$ in. Six years ago standard practice was to use $\frac{1}{8}$ changes in gauge for 6-in. changes in length of steel. The steel now used is $1\frac{1}{4}$ hexagon hollow F.I.A.B. No. 10, without lugs. There are 55 Leyner machines in use, of which 35 are using steel with $\frac{1}{16}$-gauge changes. The other 20 have not yet been changed over from $\frac{1}{8}$ intervals.

The rapid strides made in improving drill-bits and drill-sharpening methods have followed the introduction of the Carr bit and are the result of the study of its peculiarities. The Carr bit now used is essentially different from the bit originally designed by Mr. Carr. The original Carr bit had a single cutting-edge, finished at an angle of 120°, with an enlarged hole in the middle. The wings of the bit were formed on a true cone with a taper-angle of 5°, and the flat sides tapered toward the cutting-edge at 4°. In many instances all of these angles have been changed, and the bits are not made on a true cone. It is essential that the two ends of the cutting-edge and the four corners, where the faces of the bit meet the flattened sides, should cut the same circle. This necessarily means that the circle on which the wings are formed shall be larger in diameter than the gauge of the bit, the diameter being determined by three factors, namely, the angle of the cutting-edge, the taper of the wings, and the thickness of the bit at the corners. A change in any one of these factors changes the diameter of the wing-circle. In some kinds of ground Carr bits are not a success, but the principles of their design are equally applicable to cross-bits, and there is no reason to believe that with them results will not be as gratifying.

Following is a brief description of the drill-sharpening methods in use at the Cliffs Shaft mine: Three kinds of steel are used, $1\frac{1}{4}$ hexagon hollow steel for Leyner drills; $1\frac{1}{4}$ round solid steel for $3\frac{1}{4}$ piston-drills, and 1-inch round solid steel for raising-drills. Two styles of bit are used on the Leyner steel: cross-bits and Carr bits. The cross-bits are sharpened in a No. 3 Leyner sharpener, and are gauged in the dies. The gauge-changes are $\frac{1}{8}$ inch, and the changes in length one foot. The Carr bits are sharpened in a No. 5 Leyner sharpener, but are not sharpened in the dies. The steel is held by the dies, and the bit is 'upset' in the open air, one dolly and one pair of dies serving for all sizes of bit. The steel is flattened between special dies, and is 'swaged' for the wings during the sharpening process in a pair of formers with 15° taper. It is upset to $\frac{1}{8}$-in. greater diameter than the gauge, and is then brought back to gauge by being squeezed in a pair of formers with 6° taper. This method of forging facilitates drawing out the corners. All cross bits are sharpened in one heat, but Carr bits often require two. On the cross-bits the angle of the cutting-edge is 90° and the taper 15°. On the Carr bits the angle of the cutting-edge is 120° and the taper 6°. All Leyner steel is made without lugs, the shanks being bored out to $\frac{3}{4}$ in., counter-sunk, chamfered, and squared, and then tempered in oil. Breakage is very low.

The solid steel for the raising-drills is sharpened in the No. 3 Leyner sharpener in the same manner as the cross-bits for the Leyner drills, the gauge changes being $\frac{1}{8}$ in. per foot. The solid steel for the piston-drills is sharpened in a Word sharpener. Cross-bits are used with the angle of the cutting edge 90° and the taper 12°. The changes in gauge are the same as for the other cross-bits. The practice of welding 'Rocky-mountain' steel onto the round steel was discontinued about four years ago.

All steel is given a forging-heat from 2 to $2\frac{1}{2}$ in. long in a No. 9 Bradley coke forge, and is allowed to cool thoroughly before being heated for tempering. The tempering heat is made as short as possible, and the bits are quenched by plunging into a tank. The tempering heat is given in a No. 11 Bradley coke forge.

Steel for the piston and Leyner machines is marked on the shank with the number of the contract to which it belongs, and after tempering is sorted and placed in a large rack, in which each contract has a pigeon-hole. The steel for each contract is made into a bundle and held together by an iron ring and wooden wedges. The contract number is then written on one of the wedges with a blue crayon.

LUCIEN EATON.

Ishpeming, Mich., May 2.

VALUE of the gold, silver, copper, lead, and zinc produced at mines in the Eastern or Appalachian States in 1915 was $29,968,369, against $11,437,707 in 1914, according to the statement just made public by the U. S. Geological Survey. The figures for 1915, compiled by James M. Hill, represent the production of 104 mines, of which 59 were gold placer mines (many of them small), 24 deep gold mines, 14 lead and zinc mines, and 7 copper mines. The metal yield was as follows: gold, 10,848 oz.; silver, 102,545 oz.; copper, 18,772,735 lb.; lead, 697,329 lb.; and zinc, 312,498,575 pounds.

GOLD received by the San Francisco mint in April totaled 180,387 fine oz., also 126,990 oz. silver. The coinage executed was $1,385,000 in eagles, $3000 in one-cent pieces, ₱118,000 in 20-centavos, and ₱9000 in one-centavos for the Philippines. The vaults contain $374,018,535.41.

Effect of Black Slate on Cyanidation

By H. Fischer

THE article on the precipitating action of carbonaceous shale in cyanide solution, by Paul W. Avery, in the MINING AND SCIENTIFIC PRESS of April 8 calls to my mind some observations made in the summer of 1915 while cyaniding some Mother Lode concentrate. These are all the more remarkable by the fact that they so closely parallel the results obtained by him. It will, perhaps, be interesting to your readers to compare the two.

The ore consists of pyrite and arsenopyrite occurring in quartz and carbonaceous slate in about equal proportions and is treated in the manner usual in this district. The gold occurs native, combined with pyrite and arsenopyrite, the latter carrying the most gold. Considerable mineral is found in the slate. As at the Esperanza,[1] crushing liberates a large part of the carbonaceous matter in the slate, and this carbon forms a film on the surface of the pulp, visible at the turn-boxes, classifiers, and mill-discharges. It assays from $2 to $12 per ton. No attempt has been made recently to cyanide this ore direct, earlier efforts having proved futile. However, an idea of the effectiveness of cyanidation may be gained from the following:

Concentrator tailing, + 60, sand, ounces	0.06
KCN strength, per cent	0.25
Time of leaching, days	9
Final tailing, ounces	0.025

	No. 1	No. 2
Concentrator tailing, − 200, slime, ounces	0.04	0.04
KCN strength, per cent	0.30	0.15
Time of agitation, hours	72	72
Final tailing, ounces	0.04	0.04

On the other hand, the concentrate is amenable to treatment by cyanide under the conditions noted below.

Preliminary experiments showed a possible extraction of 92.5%, but when the plant was put in operation the maximum extraction obtained was about 85%. The method of treatment followed in the plant closely approximated that shown to be necessary by the tests. The concentrate, after being removed from the vanners, was ground to 200-mesh in a tube-mill with water, run over amalgamating plates into a dewatering cone, thence washed into Pachuca agitators with cyanide solution sufficiently strong to raise the resultant solution to the proper strength. After six hours' agitation, the finely-ground concentrate was washed three times with barren solution and finally with water, and discharged. The tabulated results clearly show premature precipitation.

It will be noted that the figure 0.60 oz. recurs frequently as the final tailing-assay; innumerable instances similar to those tabulated indicate this to be the point at which the precipitating agent in the concentrate begins to make its action apparent. A test was then made to determine at what period of the treatment this point was reached. Samples were taken from the Pachuca tanks after every hour of agitation.

[1]Referring to Mr. Avery's article.

Assay of concentrate discharged from Vanners	Pachucas	1st wash	2nd wash	3rd wash	Final tailing
Oz.	Oz.	Oz.	Oz.	Oz.	Oz.
3.78	1.74	0.35	0.99	0.60	0.60
4.42	1.10	0.66	0.56	0.72	0.72
3.38	0.52	0.78	0.70	0.65	0.60
3.60	0.82	0.26	0.38	0.66	0.60
3.50	0.76	0.50	0.40	0.50	0.50
3.70	0.58	0.40	0.54	0.38	0.40
3.90	0.74	0.62	0.60	0.60	0.56
4.00	...	0.62	...	...	0.60

	Gold, Oz.		Gold, Oz.
Pachuca heading	4.26	After 6th hour	0.72
After 1st hour	0.92	" 9th "	0.58
" 2nd "	0.84	" 12th "	0.60
" 3rd "	0.84	" 18th "	0.58
" 4th "	0.72	" 24th "	0.66
" 5th "	0.92		

It will be seen that most of the dissolution takes place in the first hour, and it might be assumed that a change of solution at that time would be beneficial. A test along this line showed that upon changing the solution every two hours, the residue fell more rapidly in value:

	Gold, Oz.		Gold, Oz.
Pachuca heading	4.26	After 2nd agitation	0.61
After 1st agitation	0.84	" 3rd "	0.56

This shows a residue after 6 hours' agitation of 0.56 oz. by frequent changes of solution as contrasted with 0.72 oz. without changing.

At this point it became desirable to investigate, by analysis or otherwise, the cause of the high tailing and premature precipitation. Facilities were not available for analysis and it was postponed to make a search for remedies. This was made along three lines: roasting, fine grinding, and some form of wet desulphurization or oxidation.

Roasting followed by cyaniding gave variable results, depending on the quality of the roast. The best extraction was obtained from concentrate in which the iron had been most nearly completely oxidized.

Raw concentrate, Oz.	Cyanide tailing, Oz.	Roasted concentrate head, Oz.	Final cyanide tailing Oz.
5.10	2.10	2.70	0.44
3.60	0.60	0.77	0.155
3.60	0.60	0.77	0.125
5.10	2.10	2.70	0.20
5.10	2.10	2.70	0.14

The low tailing from roasting and cyaniding confirms the results obtained at other plants having to deal with graphite or carbonaceous ore,[2] but this method increases the cost of plant and necessitates much handling of the ore, thus raising also the cost of operation. Besides, the loss in roasting concentrate lowers the apparently high extraction of 97% to a recovery of only 90 to 93%,[3] and this may be obtained by other and cheaper means.

Prolonged grinding of a portion of the concentrate with weak cyanide solution produced a marked improvement. This was done in consequence of a classification test that showed more gold in the heavier—not coarser or finer—portion of the concentrate.

No. 1	Classifier	product	0.60 oz., first to come off classifier
" 2	"	"	0.68
" 3	"	"	0.49
" 4	"	"	0.89
" 5	"	"	1.44 last or spigot product

It was so arranged that No. 4 and 5 products were constantly returned to the mill for longer treatment. At the same time strong solution was employed in the agitators. An increase of 5% in the extraction was noted:

Mill heading	Mill discharge	Pachuca discharge	Final tailing
3.76	1.92	0.48	0.42
4.80	1.40	0.48	0.40
3.62	1.38	0.40	0.32
4.82	0.96	0.44	0.38
4.52	0.78	0.40	0.40

Preliminary washes before agitation in the Pachuca tanks employing chemical reagents such as solvents for gold, arsenic, and pyrite, and various oxidizing agents, followed by treatment with cyanide solution, gave indifferent results. Lead oxide and acetate, acid and alkaline washes, alkaline sulphides, cyanogen halides, permanganate, hypochlorite, and many other reagents were tried. Attempts were made to duplicate the results obtained in roasting: to break down the iron and arsenopyrite in the wet way. There follows a list of the most active substances, together with the final tailing-assay, in ounces of gold per ton, obtained using them.

NaOH	H_2SO_4	Na_2CO_3	KBr	$(NH_4)_2S$	NaOH+Al
0.50	0.52	0.40	0.50	0.48	...
...	0.45	0.52	...	...	...
..	0.66	0.64	0.50	...	...
...	...	0.30	0.34	...	0.30
...	...	0.33	...	...	...
...	...	0.38	...	...	...
...	...	0.37	...	...	...

The best results in the wet way were due to the use of Na_2CO_3 which had been employed with the idea of dissolving the arsenious sulphide. Its action was explained in the same manner as that of prolonged grinding of the heavier concentrate particles: it prepared the auriferous material for better contact with the cyanide solution. However, the premature precipitation continued, but to a less degree.

[2]Donald Foster. M. & S. P., Feb. 5, 1910.
[3]W. R. Feldtmann. M. & S. P., May 22, 1915.
[4]Chas. Butters. M. & S. P., Nov. 20, 1915.

Mill heading	Mill discharge	Residue 1st	2nd	3rd	4th	5th	Tailing
5.01	0.90	0.56	0.44	0.50	0.48	0.40	0.35
4.82	0.96	0.50	0.42	0.44	0.40	0.44	0.38

A grading analysis of the concentrate was made to discover if the presence or absence of slate in the sulphide would affect the residue-assays or the extraction of the gold.

Mesh	%	Assay	
+ 40	2.5	$6	mostly slate
+ 60	3.5	76	" "
+ 80	3.0	127	a little slate
+ 100	6.0	127	" " "
+ 200	20.0	57	imperceptible amount of slate
— 200	64.0	101	" " " "

The above immediately suggested a means of getting rid of the carbonaceous matter, for the peculiar cleavage of the slate persists through the different stages of crushing and the large diameter opposed by the slate particle to a screen-opening as compared with that of a particle of sulphide of the same classifier-grade makes this method of separation possible.

A lot of concentrate was then screened through 60-mesh, the over-size returning for re-concentration, the under-size again classified to separate out more gangue, and the enriched spigot-product treated by prolonged grinding in weak cyanide solution with the following results, in ounces of gold per ton.

Mill heading	Mill discharge	1st residue	Tailing
3.44	0.48	0.42	0.36
3.44	0.48	0.42	0.31

To check the action of the slate on the gold-bearing solution, a piece was ground as fine as the concentrate and placed over-night in gold solution, the flask being shaken three times during the first hour, and the contents allowed to settle till next day.

Ground slate, Gm.	Amount Sol., Cc.	Before treatment, Oz.	After treatment, Oz.
150	1000	0.304	0.207
100	1000	0.304	0.236

27% of the gold in solution precipitated in 16 hours.

The case seems to have been clearly stated by M. W. von Bernewitz[5] in his article on the Mother Lode. The cause of the premature precipitation doubtless lies in the slate. His mention of the use of caustic soda is significant. However, the success attained by the use of sodium carbonate made further tests in this direction advisable. Moreover, this salt offers a great many advantages: primarily its cheapness, also its susceptibility to control, and lastly, the important fact that it produces the lowest tailing of all the agents tried. A combination of fine-grinding and carbonate wash seemed better practice than interposing a carbonate wash between two series of cyanide treatments. Therefore, a lot of concentrate screened through 60-mesh was ground in the tube-mill with a 5% Na_2CO_3 solution followed by dewatering, and agitation in cyanide solution. The results justified the method:

[5]M. W. von Bernewitz. M. & S. P., Jan. 3, 1914.

Mill heading	Mill discharge	Pachuca agitator Heading	Pachuca agitator Discharge	Final tailing
Na_2CO_3 solution		KCN solution		
Oz.	Oz.	Oz.	Oz.	Oz.
3.36	1.88	1.58	0.22	0.22
3.36	1.42	1.58	0.24	0.24
3.36	2.22	1.58	0.22	0.22

Consumption of the Na_2CO_3 in the mill was 0.65%. The Na_2CO_3 raised the KCN consumption somewhat, but did not affect the precipitation. Decantation, water, and lime washes were used to get rid of the Na_2CO_3.

Zinc-box No.	Head solution, Oz.	Tail solution, Oz.
1	0.65	0.01
2	0.64	0.03

The extraction obtained by these means remains at about a minimum of 93–94%, increasing with the value of the concentrate. This agrees very well with the preliminary tests for cyanidation. The object of the tests having been attained, the matter was dropped. The function of the Na_2CO_3 and the action of the slate was outside the scope of these experiments, so no explanation based on research can be given. However, it would be interesting to speculate on just how the Na_2CO_3 and slate accomplished their effects.

A lot of ore from a mine lying outside the slate belt and not known to contain arsenic was treated both with fine-grinding and straight cyanidation, and also with a Na_2CO_3 wash. The results were the same. Concentrate from this ore likewise failed to give higher extraction with the Na_2CO_3.

1.62	0.14	92½
1.52	0.11	92
	With Na_2CO_3	
1.62	0.12	92½

In this ore the tailing is amenable to cyanide, whereas the graphitic ore is not. In this concentrate the Na_2CO_3 affords no improved extraction as in the case of the graphitic concentrate. The Na_2CO_3 appears to be active only in the presence of such reducing agents as the carbonaceous slate and the arsenious sulphide; what action it can have on so inert a substance as graphite is inexplicable unless the CO_2 liberated by hydrolysis and the action of arsenious sulphide becomes adsorbed by the slate; and as it is rather an oxidizing substance, it neutralizes the precipitating action of the slate merely by its presence. That is to say, neither the graphitic slate nor the carbonate do of themselves enter into either a reducing or oxidizing action, but they would, if either were alone, cause one to be brought about. The carbonate, therefore, makes impossible the conditions necessary for precipitation by carbonaceous material. But the action of the Na_2CO_3 on the arsenic is known. An authority gives it as $NaAsO_2 + NaAsS_2$.[6] This is soluble and is removed by decantation and washing with water, or, if a higher oxidized form is presumed, lime solution could be used as suggested by Andrew F. Crosse.[7] This latter action also removes traces of the original Na_2CO_3 not otherwise eliminated. What becomes of the acid radical of the carbonate is ascertained in the subsequent cyanide treatment, for the cyanide consumption immediately indicates whether or not CO_2 has been carried over by the concentrate, and it usually has been.

Another fact worth noting is the great difference in the value of the mill-heading and the discharge when grinding in Na_2CO_3 solution. An assay of the solution shows the presence of gold in quantity sufficient to compensate for the difference mentioned. The assumption is that the carbonate solution dissolves the gold, which becomes $NaAuO_2$ in the same manner as the arsenic. Whatever the action of the alkali may be, whether as a solvent for gold and arsenic or merely as a guardian over the conduct of the graphite, Mr. Avery's idea of the oxidizing effect is a very plausible one.

Summing up, it may be said that concentration, classification, and screening play important parts in the elimination of the graphite. Mechanical methods will remove the slate while the Na_2CO_3 is expected to take care of the arsenic. As for the original ore, which was shown at the beginning to be not amenable to cyanide, it responds readily to flotation. The communication promised by Mr. Avery on this subject is awaited with interest. The ore here, as concentrator tailing, offers to flotation the head assay of 0.025 oz. gold, yielding 1.11 oz. concentrate and a tailing assay of 0.004, but the action of the slate persists. It obtrudes itself upon the flotation concentrate as it does upon the table product and even to a greater degree, but it is expected to overcome this difficulty similarly.

SHEET-STEEL and iron, containing copper, show greatly increased corrosion resistance when exposed to atmospheric conditions. The most effective amount of copper to be used for this purpose is approximately 0.25%. Smaller quantities of copper, down to as little as 0.04%, have a considerable influence in lessening corrosion, but the results are not so good as with the higher amount. Previous investigation has indicated that 0.15% copper is in nearly all cases as efficient as 0.25%. Copper up to 2% gives little or no added benefit. Copper is as necessary in the so-called pure irons to insure corrosion resistance as it is in normal open-hearth and Bessemer steels.—D. M. Buck and J. O. Handy in *Jour. of Ind. and Eng. Chem.*

ASBESTOS PRODUCTION of the United States in 1915 was 1731 tons worth $76,952, an increase of 39% in quantity and 306% in value.

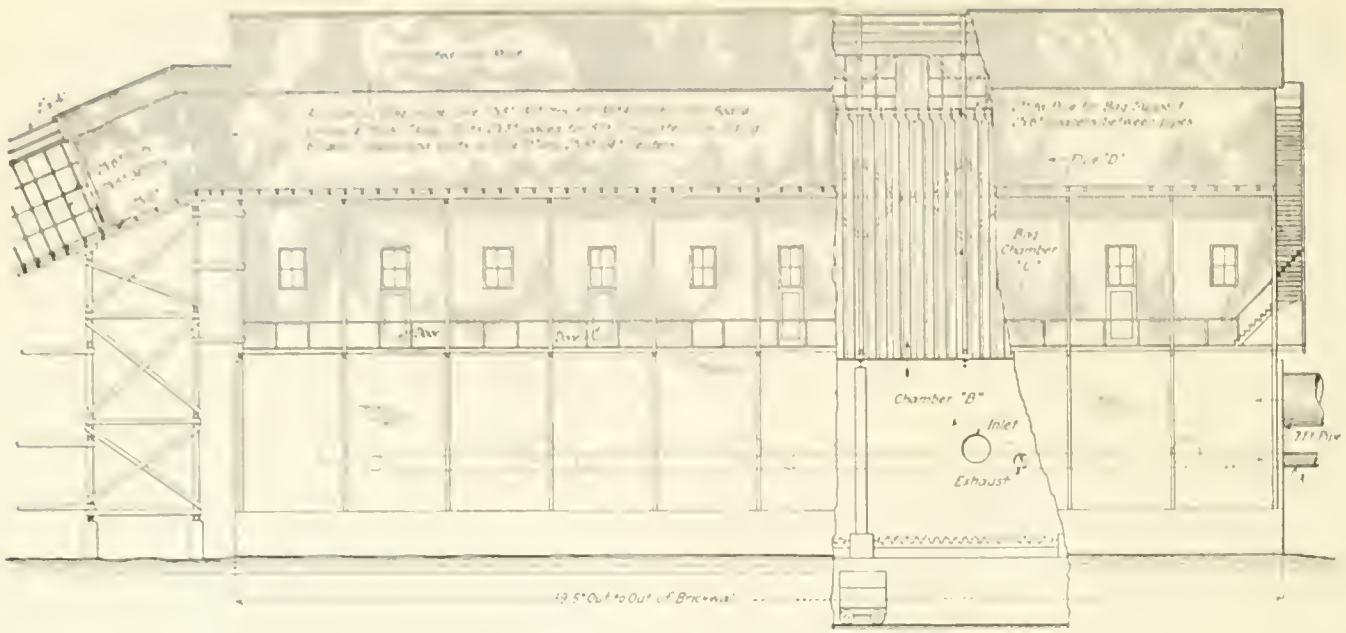

FIG. 1. LONGITUDINAL ELEVATION OF THE BAG-HOUSE.

The New Bag-House at the Midvale Smelter

By L. S. Austin

THE filtering of flue-dust from escaping furnace-gases through a woven fabric was successful practice as early as 1876 at the Lone Elm works, in Missouri, using the Lewis & Bartlett bag process.* The notable instances of its earlier use are at Canon City, Colorado, and at the Globe smelter, near Denver, where the details of practice were gradually developed. In the silver-lead smelting works of the West generally this method has been preferred to settling by gravity in flues or to the electro-static settling now coming into vogue.

From the time that the United States S. R. & M. Co. entered the silver-lead smelting field they have made use of the bag-house, at first after the blast-furnace, later for roaster-fume. They were driven to this, both by the saving in metal-bearing flue-dust, and by the pressure brought to bear by the agricultural community, which conceived that crops and live-stock were injured by the escape of fume into the air. The complaint was that particles of flue-dust, settling upon the vegetation, burned holes in the leaves; and that the fume contained free sulphuric acid. Filtration through bags so well removed the flue-dust that today it is difficult to detect by looking at the top of the stack that gases are escaping. The Sprague system of neutralizing the free sulphuric acid has overcome the second objection. While by order of the court a maximum of 0.75% of SO_2 is allowed in the escaping gases, this limit is not nearly approached.

Last spring, in the MINING AND SCIENTIFIC PRESS† I described the method of discharging the bag-house gases through a high stack, tending to dilution by the air; I

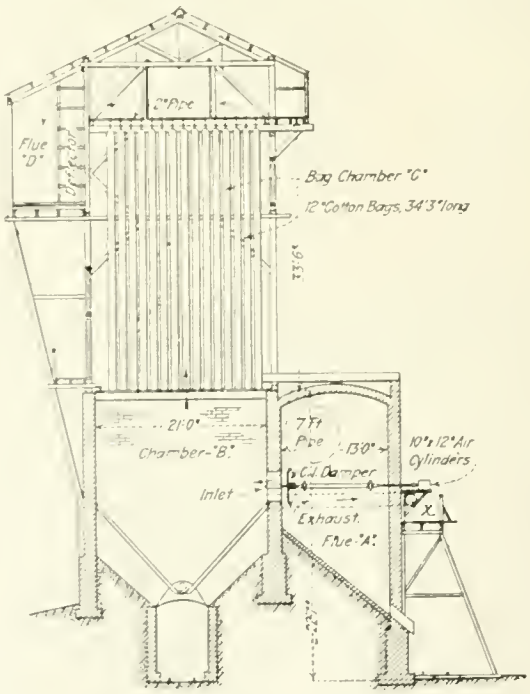

FIG. 3. SHOWING POSITION OF INLET-DAMPER AND AIR-FEEDER.

*Why a cylinder of cotton or woolen cloth 1½ ft. diam. by 30 ft. long should be called a 'bag' must be due to the shortness and convenience of the word. The gases entering and distending it escape outwardly through the meshes of the fabric.

†'Smoke Dilution at Midvale.' M. & S. P., April 10, 1915.

propose now to give the details of further improvements in disposing of the gases from the six blast-furnaces.

In calculating the capacity of the new bag-house it had to be considered that five out of the six furnaces would be running, these five taking the air from a blower of 175 cu. ft. per revolution at 160 r.p.m., or, allowing for 5% of slip, equal to 26,600 cu. ft. per min. The temperature of this air, entering the blower at 40° F., would be 200° F. at the top of the charge, expanding by one-third, to 35,470 cu. ft. Allowing for the other furnace, and for a considerable leakage through the furnace-top covers, as well as for additional air admitted to lower the temperature at the bag-house to 150° F., a fan capacity of 60,000 cu. ft. was needed. For this a No. 14 Sirocco fan is used.

From the main brick flue, back of the blast-furnace, a 12-ft. elbow leads to a 12-ft. balloon-flue 127 ft. long, forming the 'trail' leading to the No. 14 Sirocco fan. Just before entering the fan at the top of the flue, there is fed a regular supply of finely ground quicklime. This, mingling with the gases, neutralizes any H_2SO_4. Naturally the fan-blades ensure a thorough mixing; in addition, the quicklime particles adhering to the bags also assist in the neutralization. Since the total bag-surface is 324,000 sq. ft., this is equivalent to a diffusion of gas through the cloth meshes at the rate of a foot per five minutes. As in any filtering operation, the more open texture tightens, since the faster flowing gases at that point more quickly deposit their load, thus averaging the flow.

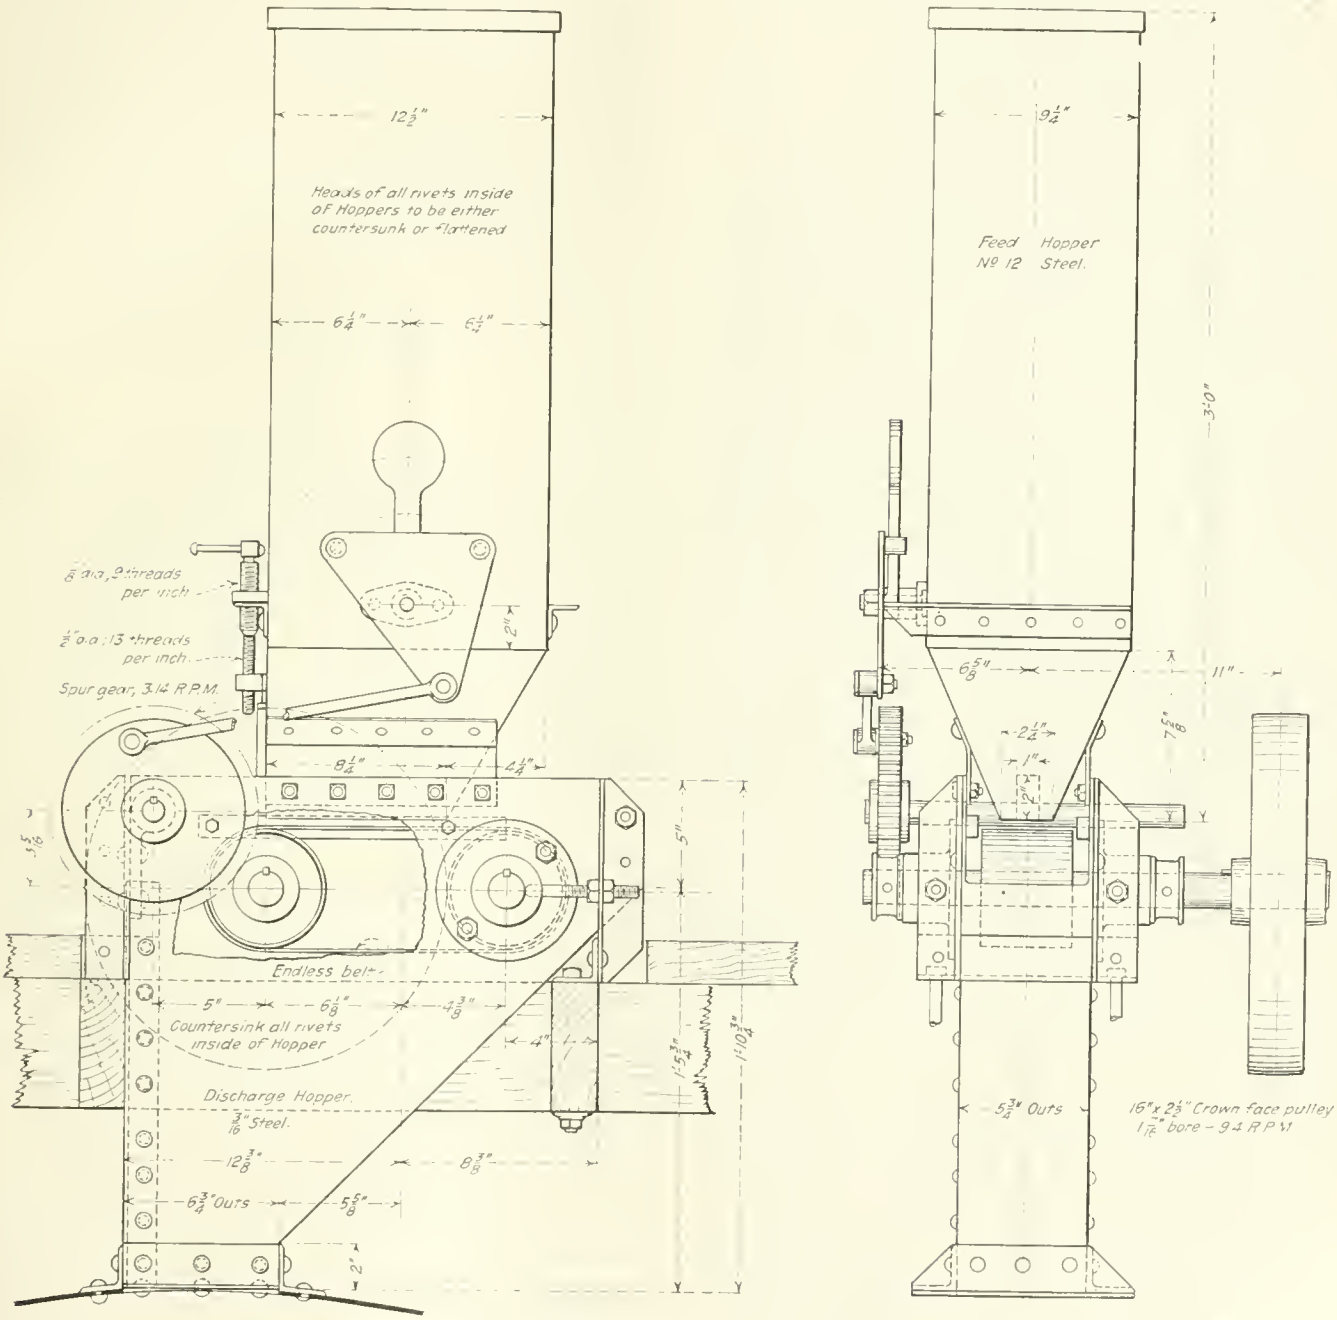

FIG. 2. THE LIME-FEEDER.

Referring now to Fig. 1, showing a longitudinal elevation of the bag-house, it is seen that the lower brick construction is double. This was an old double flue upon which a framed superstructure has been set. From the fan the gases enter the flue *A* (see also Fig. 3) by a 7-ft. pipe. The adjoining main chamber, which consists of the dust-chamber *B* and the bag-chamber *C*, is divided transversely into five compartments or bays. Each bay has an admission or inlet-pipe and an exhaust pipe, both controlled by disc-valves. By adjusting these valves, any bay may be shut off and an exhaust connection opened, thus collapsing the bags, and so loosening the flue-dust that has accumulated on them. The exhaust-pipe is branched into the exhaust-main *X*, this leading back to the 'trail' on the exhaust side of the fan. Once during a shift the valves are operated, and after each shake a 5-minute interval is allowed in order to give the dust an opportunity to fall into the lower chamber. Once in several days the bags are given a 'hand-shake' to clean them more thoroughly.

The bottom of the dust-chamber is inclined at 50°. When the bag-house was started, these grades were much flatter, and the dust was expected to form its own slope, but it tended to arch over the feed-screw and harden there, so that the steeper slope of sheet-steel had to be used. Besides this, access is obtained beneath the sheets, and by jarring them with a hammer or bar the descent of the flue-dust is ensured, the dust working down to a helical screw (one for each bay) by which it is brought to a discharge-opening under each division-wall, and thence falls into a car. The screw is started or stopped at will, being driven by a clutch taking-off from a motor-driven counter-shaft.

As the gases seep through the bags, they flow along the flue *D*, which continues at a grade of nearly 5 in. per ft. to the base of a self-sustaining brick-lined stack, 210 ft. high by 16½ ft. inside diam. This stack, which had not been used for several years, as the copper-smelting plant had been abandoned, effected an important saving in expense. For all that, the new bag-house cost $200,000.

In the flue *D*, deflectors are placed to turn the gases leaving the dust-chamber into the direction of the flow. The velocity of the gases here is 9 ft. per sec.; at the stack the flow is nearly 5 ft. per sec., certainly a low figure

In the older types of bag-houses, the sides and roof were of corrugated iron, and a free escape was permitted from the bag-chamber through shutters, sometimes by stacks surmounting the house. But the cooling of the fume resulted in a condensation of moisture, the dripping of which soon contributed to the destruction of the bags. In this plant it will be seen that, besides the outer covering, there is an inside one of asbestos, in sheets 36 in. wide, nailed to the studding. The outlet-flue *D* is lined on three sides with ⅝-in. tongue-and-grooved stuff, and all round with No. 22 copperized sheet steel.

The thimble floor above the lower chamber is $\frac{3}{16}$-in. sheet steel carried by 12-in. I-beams. The thimbles themselves are 10 in. high by 11 in. diam., there being 240 to each bay, or 1200 in all. The bags, 34 ft. long, are made from 42-in. canvas, double sewed with inch lap. These are wired at the bottom to the thimbles and suspended above from 2-in. pipes.

Fig. 2 is the lime-feeder driven by a counter-shaft from the fan-shaft. The hopper is tall and narrow. The finely ground quicklime falls upon an endless belt, passing thence to the top of the 'trail.' To prevent lodging in the hopper, a triangular plate is hinged and vibrated by means of a link from the drive-shaft. A loosely-swinging hammer is actuated by stops on the upper corners of the plate. It falls with a jar upon each stop and shakes the hopper.

Fig. 3 shows the general arrangement of the inlet-damper and the air-cylinder that actuates it, as well as the walk-way and the flue. The smaller damper of the exhaust is moved by a simple stem and handle, central in the branch exhaust-pipe, but not shown in this drawing.

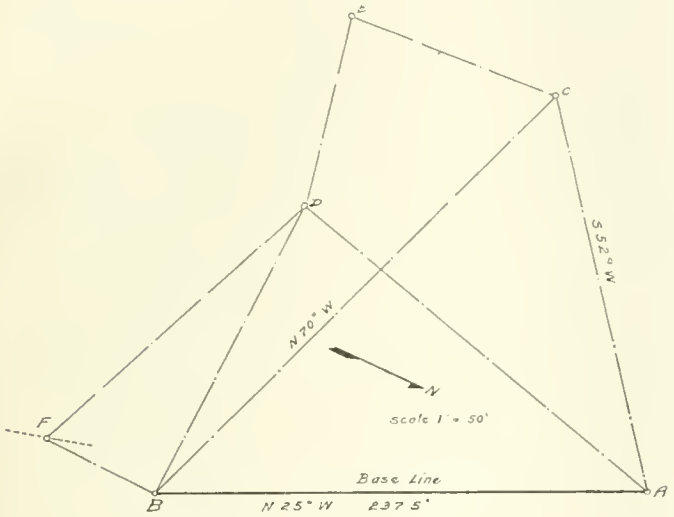
NICKEL OUTPUT. The International Nickel Company, which operates nickel-copper mines in the Sudbury district of Ontario, under the name of the Canadian Copper Co., is said to control 80% of the world's nickel production. The Creighton mine at Sudbury is the principal source of supply, but the company also owns mines in New Caledonia, the French island half-way between Australia and the Fiji Islands, which is the only serious competitor of Ontario as a nickel-producer. The New Caledonian deposits consist of a large number of small veins richer than at Sudbury; they are capable of yielding a much greater output than at present. The world's production of nickel is 60,000,000 to 70,000,000 lb. per year, and the price is usually 40 to 50c. per pound. Nickel is used extensively in the manufacture of armor-plate, which contains 3 to 4% of nickel, and in structural steel; the automobile industry is requiring an increasing amount of nickel both for toughening steel and to plate attractive surfaces: miscellaneous uses, such as for making German silver, consume a good deal of nickel. As regards the recent request made by the Canadian government upon the International Nickel Co. to refine its matte in Canada rather than in the United States, the objection made by the company to refining at Sudbury is the high price of fuel at that place. Nova Scotia is favored as a site on account of its coal supply and ocean transport, but the American import tax of 10% on refined nickel would be a disadvantage for refining, in Canada, nickel for use in the United States. Dividends of International Nickel Co. on its common stock have varied from 10 to 20% during the past five years; the common stock amounts to $41,834,600 while preferred stock, bringing 6%, amounts to $8,912,600. Occurrences of nickel ore in the United States, while unimportant, have been noted in Lancaster county, Pennsylvania, at Mina La Motte, Missouri, in Douglas county, Oregon, near Webster, North Carolina, at Lovelock, Nevada, and at San Diego, California.

A Quick Method of Locating Geologic Features

By Charles A. Porter

In the examination of prospects, an approximate method of determining the position of landmarks is often desired. The method here outlined is of value in avoiding gross errors in the location of geologic features. As there are no measurements after the base-line has been determined, the aid of an assistant is not required.

The system is a method of triangulation using the Brunton pocket-compass, or any other good compass, making notes and plotting them at leisure. The system involves no calculation, the course and distance of the points on the map being determined by platting to scale. The principle involved is that used in the operation of the plane-table.



A TRIANGULATION SURVEY.

In the sketch we will suppose the base-line *A B* to have been measured and its bearing determined by the needle. In this case we will assume that the course and distance is N 25 W, 237.5 ft., odd figures being no inconvenience owing to there being no calculations.

To determine the location of point *C*, first sight with the compass on *C* from *A* on the base-line, noting the bearing. Then from the other end of the line at *B*, sight again on *C*, entering the courses in the note-book. This completes the field work necessary to determine the location of *C* with reference to the base-line.

The base-line is platted, giving it the course and distance determined in the field. A line is then drawn from *A*, having the same course shown from *A* to *C* in the field notes. The course from *B* to *C* is then platted, the line being prolonged until it intersects the line drawn from point *A*, the intersection determining *C*. Point *D*, or any other point visible from *A* and *B*, may be located in the same manner, showing the relation between *C* and *D* as well as with the base-line.

The bearings of as many points as convenient may be taken. Reflection will show that the process can be carried on indefinitely and is not limited to points visible from both ends of the base-line. Once the points *C* and *D* are located, the deduced course and distance between them can be used as a basis for further survey, such as to determine *E*, which is invisible from either end of the original base-line.

In locating the point *F* the course and distance *B D* should be used as a base instead of the original *A B*. It is obvious that slight errors in reading the needle would become exaggerated and would tend to throw the point *F* a considerable distance along the direction shown by the dotted line.

Nevada's population has fluctuated with the prosperity of its mines, and 'ghost cities of Nevada' is the term used to designate abandoned settlements where mining booms dwindled to nothing. In 1870 the population of the State was 42,491; in 1880 it had increased to 62,266. Of this number, it was estimated that 42,019 were males and 20,247 females. Fully 25,000 of the population was foreign-born, and probably 5000 were Chinese. The two centres of population at that time were the Comstock lode in the extreme western part, and Eureka in east-central Nevada. In 1890 the State had 47,355; and in 1900 only 42,335—a decline due to the fall in the demand for silver. In 1910, the population had increased to 81,875; while today it is about 100,000.

San Francisco's population of 500,000, with the 250,000 of Oakland and the 60,000 of Berkeley, is the nucleus of the million people who live around San Francisco bay. As regards mining, San Francisco has, of course, been a famous distributing centre for mines since the boom days of '49. The great valley of California, 500 miles long, extending between the Coast ranges and the Sierra Nevada, has its natural outlet to the ocean at San Francisco, and the excellence of the harbor gives the city an advantage for shipping, not only to Pacific ports but to others. San Francisco is the largest city in the western two-thirds of the United States, and with the exception of St. Louis the largest west of the Mississippi river.

Denver has a population of over a quarter of a million, which is as much as the entire State of Arizona, and more than Nevada or Wyoming. The city has long been recognized as a centre for Rocky Mountain mining, particularly for those districts along the eastern fringe of the Great Basin. Its altitude is about a mile. With the increase of agriculture in Colorado, Denver will become a ranching and farming centre. While gold and silver mining in Colorado is declining somewhat, a variety of important minor minerals are being discovered and worked.

The porcupine district will produce during 1916, it is estimated, about $15,000,000 in gold. The silver output of the province of Ontario in 1915, mostly from the Cobalt district, was $11,742,463. Ontario's importance as a gold producer is increasing.

Stoping by Branched Raises

By F. W. Sperr

LET us assume an irregular lenticular orebody. Fig. 1 represents the horizontal outlines of such an orebody at 25-ft. intervals. The wall-rock and capping are strong, and the ore is of medium hardness and texture. Therefore large chambers of ore may be extracted without caving or in any way disturbing the enclosing rock. The main considerations in applying a stoping method are: safety to the workmen, the elimination of timber, and the reduction of shoveling and tramming. It appears that the ore may be extracted from the top downward, leaving the opening self-supporting, thus eliminating the use of timber. The reduction of shoveling and tramming may be accomplished by a suitable arrangement of 'mills' into which the ore falls as broken, and from which it may flow directly into tramcars on the main-haulage levels, under control by suitable chutes.

The first haulage-way will be on the foot-wall 100 ft. below the top of the ore. Four vertical raises will be driven on the foot-wall side, 45 ft. apart and designed to be near the hanging wall at the top sub-level, which in this case is 75 ft. above the haulage level. If no other raises were used, a great deal of shoveling and tramming would be necessary in the stopes; therefore, branched raises are started from the main vertical raise in such a way as to cut up the block of ore most advantageously for reducing the shoveling and tramming. For maximum efficiency the raises should be 25 ft. apart on every sub-level, should reach close to the foot-wall, and should approach the hanging wall according to its dip; the steeper the dip the closer the approach.

Beginning at the top sub and working downward, drifts and cross-cuts are made 5 or 6 ft. wide and 6 or 7 ft. high on the different sub-levels to connect the raises with each other. Then the ore is blasted into the raises from around the sides, and by means of down-holes the tops of the raises are made funnel-shaped and widened, until their rims become contiguous. This leaves 15 to 17 ft. of ore in place above the cut. By means of upper holes, about 8 ft. of the overhanging ore is brought down and left lying for a foundation upon which the drills are rigged for another series of upper holes. If, in places, the ore goes up more than 25 ft. above the sub, as it often does in irregular fingers, it is mined by successive series of upper holes, or by the ordinary back-stoping-on-broken-ore method.

The sub-levels are 25 ft. apart vertically. Each sub is mined in substantially the same way as the top sub, except that the 'mills' will be better distributed on some sub-levels than on others. There will always be the balancing between the cost of extra raises and the cost of extra shoveling and tramming.

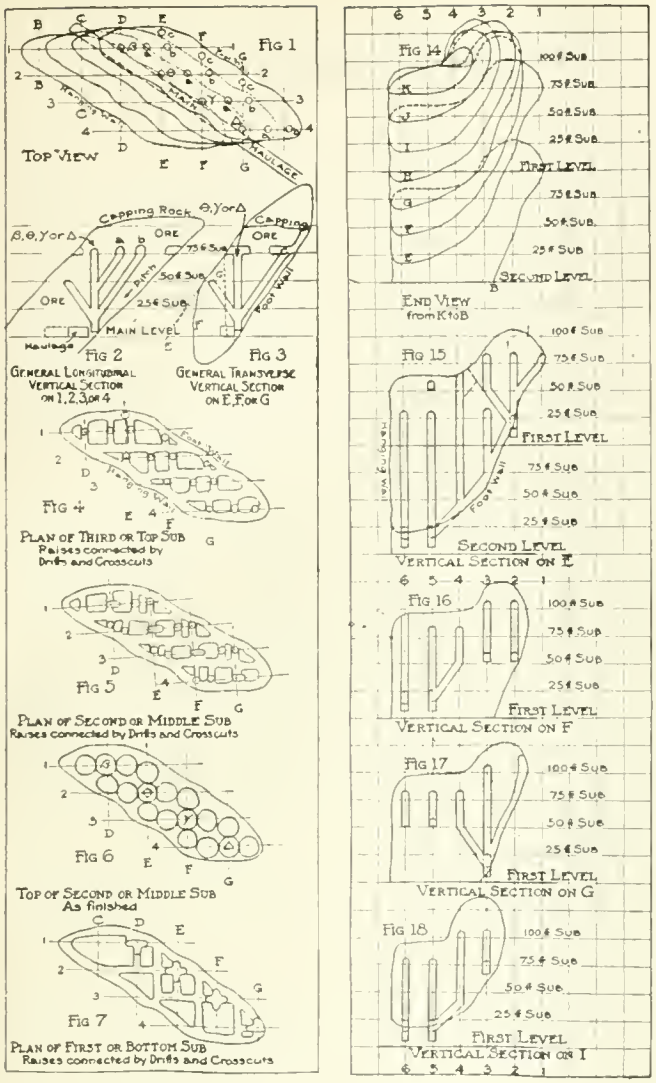
Fig. 2 illustrates any one of the different vertical sections on the lines *AA*, *BB*, and *CC*, of Fig. 1. The section on the line *DD* would show the bottom of the raise in the foot-wall rock.

Fig. 3 represents the vertical sections through the raises *B* and *C*, on the lines *BF* and *CF*, at right angles to the lines *AA*, *BB*, etc. The branches are driven in four directions from these main raises, in two sets one above the other, and at vertical angles of about 55°. The branches from *A* and *D* are driven in three directions, the fourth direction being against nearly vertical walls. By this arrangement mills are provided on the 75-ft. sub-level, and distributed in such a manner that little shoveling and tramming will be necessary. Fig. 4 shows the positions of the raises on this sub and the connecting drifts and cross-cuts. The raise *D*2 to the right is extended on the pitch of the formation.

Fig. 5 shows the positions of the raises on the 50-ft. sub, connected by drifts and cross-cuts. The arrangement of the mills at this level is nearly ideal, as illustrated by Fig. 6, which shows the approximate positions of the rims of the mills after being funneled out. Hog-backs of ore will be left lying on the spaces standing between the mills. All this goes down with the next lower sub. But along the foot-wall, all broken ore has to be cleaned off to the sub-floor. Otherwise it is liable to 'hang-up' instead of coming down with the next lower sub; therefore it is desirable to have the raises along the foot-wall close enough together and close enough to the wall to prevent any considerable quantity of ore from finding lodgment.

The branched raises are available for mills on the higher subs, but not on the first sub above the main level. Fig. 7 shows all that remains of the raises on the 25-ft. sub-level. Only the main vertical raises are left; but these are well distributed along the foot-wall, making the amount of shoveling and tramming the least possible under the circumstances. If the ore does not extend below the main level, immediately under this sub, it will probably be more economical to do the shoveling and tramming, than to provide more mills together with the necessary chutes. But, if the ore extends downward so that another main level becomes necessary, some of the ore from the 25-ft. sub may best go down to this next lower level through some of the mills, which may be extended upward as required. Ordinarily the ore from each main-level slice is milled to the chutes of the next lower level.

Various names have been given to this method of mining. It is variously known as 'subbing,' 'underground milling,' 'slicing without timber' and 'sub-slicing without timber.' The last term seems the most distinctive.



DETAILS OF STOPING BY BRANCHED RAISES.

It suggests the method of operating and does not apply to other methods, while all of the other terms are used also to designate methods that are much different in detail.

Fig. 8 to 18 illustrate the case of an orebody beginning somewhat irregularly under the capping and extending downward with a nearly vertical hanging wall, and with the 'back' pitching down at an angle of 45°. The physical conditions are similar to those in the preceeding case, and the same method of mining will be applied with little difference in detail.

Branched raises from six chutes on the first level and from the same number on the second level, provide mills 25 ft. apart on every sub-level. The foot-wall sides are properly provided, and nearly all shoveling and tramming in the stopes is eliminated.

The ore is of such a character that it gives little trouble by packing in vertical raises; therefore the branches are made vertical in places for convenience of arrangement. Accessibility to the vertical mills for the purpose of relieving the tendency to pack, can be more readily provided where the branches are inclined throughout their entire length, than in the case where they are partly vertical. Softer ore has a greater tendency to pack in the mills at a high angle, as well as to hang up in the mills at lower angles. The best angle for the worst ores, in this regard, is 65° above horizontal, but some ores run freely at an angle of 45°.

The developments from the second level are as yet only prospective; but it is reasonable to suppose that the ore will go down another 100 ft. judging from the developments of the first level. The second level should be developed no earlier than necessary for continuous production to follow the exhaustion of the first level; for by long standing the chutes decay and the openings cave, and the whole foundation may be weakened to such an extent as to destroy the system of mining. Fig. 8 is a top view of the outlines of the horizontal sections of the orebody at the prospective second level and at vertical intervals of 25 ft. from the first level to the top of the

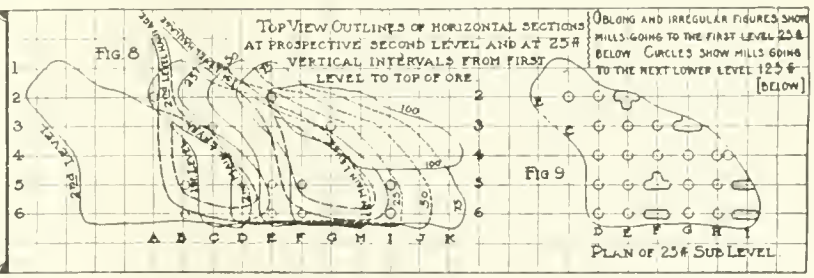
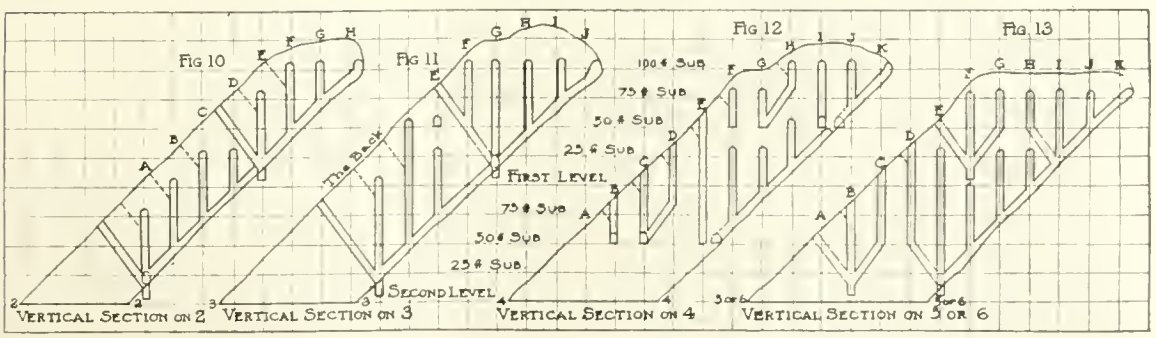
IRON ORE MINING THROUGH BRANCHED RAISES





ore. The full circles show the positions of the chutes on the first level. The dotted circles show the positions that the chutes will occupy on the second level, if there is no material change in the formation in the next 100 ft. downward. Fig. 10, 11, 12, and 13 represent vertical sections on the lines 2, 3, 4, and 5 respectively. The vertical section on the line 6 is substantially the same as the one on the line 5. These sections, together with the transverse vertical sections on the lines *E*, *F*, *G*, and *I*, as shown in Fig. 15, 16, 17, and 18, show the complete system of development of the raises for the first and second levels.

The plan of any one of the sub-levels below the irregular top, as developed by raises from two successive main levels, will be typical of all. Such a plan is represented by Fig. 9. The circles are the tops of the mills going to the second level. The oblong and irregular figures are the tops of the mills going to the first level. Plans of different sub-levels will differ from each other in little except the relative positions of the two different classes of mills.

From the method of slicing into mills without timber, it is an easy transition to a variety of different methods of mining that have been devised and adapted to ores of divers physical qualities in bodies of various shapes and sizes. When the ore is so hard that the long raises and numerous sub-levels become too expensive, the obvious thing to do is to make the raises shorter and reduce the number of sub-levels. Practically the same number of mills, similarly distributed, will be required as before; but let the raises terminate at the 25-ft. sub-level as shown in plan by Fig. 9, and let them all be started from the first level. This will make a modified plan of the level necessary, in order to give the tram-cars access to the chutes. The sub now has a back of 75 ft., instead of 25 ft.; it will be mined by upward slices the same as before, except that nine or ten slices will be required instead of two. Sufficient broken ore will be left overlying the mills to make it convenient to reach the back for the successive slices. After the stope is finished, the remaining broken ore is drawn off through the chutes. This is the full-stope method of stoping on arches.

But, whenever the capping or hanging wall, or both, begin to break or cave, another modification of the method becomes necessary. The breaking and caving can be prevented, or at least retarded, by reducing the size of the chamber. Instead of making one continuous stope, pillars may be left standing in a variety of ways to divide the stope into self-supporting rooms. In the design of such a method, provision should be made for the ultimate recovery of the ore in the pillars, either by crushing or caving, not only for the salvage of the ore, but more for the safety of the mine. This is the method of back-stoping by rooms.

COPPER production of Michigan in 1915 was 238,956,410 lb. (a record), compared with 158,009,748 lb. in 1914, and 231,112,228 lb. in 1912. Ore mined and treated totaled 12,334,699 tons, yielding slightly over 1% metal. The silver recovered was 585,933 ounces.

Rifled Cores in Diamond-Drilling

Phenomena of rifled cores are due to tortional vibration of the drill-rods, which in turn is produced by the rotation of the rods. The cutting medium attached to the rods engages with the core, penetrating to a certain depth, and thereby temporarily checking the rotation of the rods. When the energy stored up in the rods by the tortional strain exceeds the frictional resistance between the cutting medium and the core, it forces the cutting-point out and the rod springs around until the strain is relieved, the action being repeated uniformly and indefinitely. The depth to which the cutting-point enters the core depends on its size, shape, and hardness, and on the hardness of the core, also on the intensity of the vibration. The distance through which the cutter rotates between points of contact with the core determines the number of threads to the turn, but it is probable that the number once established pre-disposes its regularity and symmetry. With lower speeds of rotation the vibration is less intense, and the cutting-point remains in contact with the core for a longer period; the number of threads to the turn as well as the pitch of the threads may be changed in this manner.

The conclusions reached by investigations may be summarized as follows:

1. Riflings of cores are produced by tortional vibration of the rods.

2. The formation of multiple threads, or a number to the turn, is determined by the intensity of vibration, character of the cutting medium and the core.

3. The pitch of the threads is determined by speed of rotation of the rods.

4. The size and length of rods probably act only indirectly to modify the size, shape, and pitch of threads.

As rifling of core is produced by rotation and varies in prominence with the intensity of vibration, it is possible to prevent or materially reduce the vibratory action of the drilling mechanism by reducing the speed of rotation of the rods. This method of procedure would undoubtedly be much less difficult and troublesome and far more efficacious than the practice of greasing the line of rods.

It is possible that aside from the desirability of knowing how rifled cores are formed, the knowledge may be of little or no importance, yet who can say when a purely scientific fact may not become of considerable economic value. Many engineers and diamond-drill companies considered that vibration was responsible for rifled cores. —Walter R. Crane in paper prepared for the Arizona meeting of the A. I. M. E.

ZINC IN MONTANA increased in value of output from less than $6,000,000 in 1914 to $26,000,000 in 1915. The increase in spelter output was 60%. Montana produces less than $5,000,000 annually in gold. The State's production of copper was 268,000,000 lb., being less than that of 1913, despite the better price.

The Gasoline Question

By an Occasional Contributor

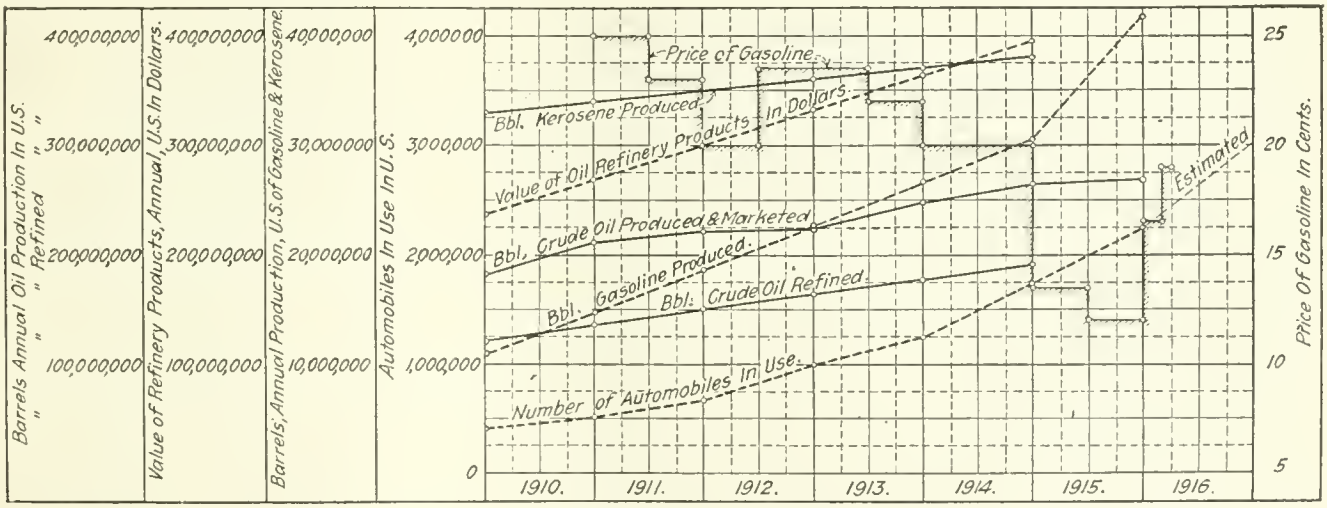
MUCH has been written lately in a hysterical way, and much ranting has been done in legislatures and in the halls of Congress on the subject of gasoline and its sudden rise to what seems to be considered by the consuming public an iniquitous price. Succinctly, the public wants to know if the rise is warranted; is it due to that industrial Machiavelli, Standard Oil. Parenthetically it may be asked, is the present level of prices, in view of conditions, at all abnormal?

Be the answer what it may, the public's interest lies largely in what can reasonably be expected in the future in regard to both supply and price for what has become a most important staple of commerce. The public asks the professional man on the one hand, what avenue of relief is there for this new situation, and on the other hand requests the Attorney-General to state what, if the cards are stacked by the aforeascribed machiavellian trust, is he going to do about it?

The question has had the dignity of a resolution passed by the U. S. Senate, where, unfortunately, political fences are sometimes built in anticipation of coming elections, and has for months occupied the attention of the Federal Trades Commission. In reply to the Senate resolution our well-informed Secretary of the Interior reported to Congress clearly, at length, and to the point that it is only a natural situation, while the newly-created Trades Commission has rendered thereon a preliminary though somewhat non-committal report. The following data, observations and impressions are taken mainly from these reports, and from the U. S. Census, as well as from published interviews with prominent factors in the oil business—the producers and refiners themselves.

In the ordinary course we look for guidance to general principles. The law of supply and demand is one of these, and has been generally accepted as ruling in every-day affairs. There is no reason why it should not apply in this case, barring special conditions that obtain in every particular industry.

The graphic exhibit, Fig. 1, gives the relation for the past five years between the production of the raw product, crude oil, and the various elements that enter into an intelligent comprehension of the problem. There



Graphic Diagram showing relation for past Five Years, between production and consumption, of various elements of the Petroleum Industry, in the United States, as compared with the increase in number of Automobiles in use.

FIG. 1.

are, of course, other factors, but these are the leading ones (referring only to the production of the United states), to wit:

Group 1. (*a*) The amount of crude oil produced annually; (*b*) the amount of crude oil refined annually (the difference being consumed as fuel?); (*c*) the amount of kerosene produced annually, and considered as consumed (which it is not, of late).

The curves for these three elements are substantially parallel and indicate what might be considered a normal situation in the oil business.

Group 2. (*d*) The amount of gasoline produced annually, and considered as consumed; (*e*) the number of automobiles in use in the United States; (*f*) the total value of the refinery products.

The elements of Group 2, it will be seen, are also roughly parallel, and the sharp rise of these curves over those of Group 1 carries its own meaning. Unfortunately for the public, the raw product, crude oil, is in

Group 1, and it is more likely than not to remain in that position if those who are best qualified to speak are to be trusted. The report of the Secretary of the Interior to Congress presents data showing that the known oil reserves of the country have been drawn upon or depleted to the extent of 50%, ranging from 34% in California to 75% for the Eastern oilfields. The amount remaining, about 7,500,000,000 bbl., is not all commercially extractable. Untested areas, of course, surround the proved oilfields; these may be assumed to be probably productive, but their value is problematic. It is the general belief that 300,000,000 bbl. is our maximum annual productive capacity, and since our oilfields have for years produced two-thirds of the world's output, and have therefore supplied two-thirds of the world's consumption (since the European War about four-fifths, because of the practical exclusion of the Rumanian and Russian oilfields) there must be a re-adjustment soon somewhere.

Superimposed upon the curves of Fig. 1 is the course of the average retail price of gasoline on the seaboard of California in recent years; the authority therefor is the *Oil Age* of Los Angeles, in its April issue. The exhibit speaks for itself; the purport of it is that the average price per gallon for the period has been 20c., and that for relatively short intervals only has it been below the average. The price today is 10% lower than it was the day the European War broke out. Prices in different parts of the United States vary both as to time and amount, being higher on one coast than the other at a given date; at present the differential in favor of this coast is 6c. per gallon, hence gasoline is now flowing eastward from San Francisco.

The obvious disturbing factor in prices at the end of 1914 was the 'bringing-in' (in March) of the famous Cushing oil-pool in Oklahoma, with its phenomenal yield of high-gravity refining oil, rich in gasoline. Its history and the attendant disturbance to crude-oil values are shown by Fig. 2. The price of gasoline has followed, and has been more influenced, by the story of Cushing than by either the European war or our domestic business disturbances or by the volume of gasoline exports. The effect was psychological as well as real; to which I may add that when the press-agents of the auto-makers at Detroit spread abroad the report that for the first quarter of the year 1916 the purveyors of this item of luxury as well as business necessity shipped just twice as many carloads of finished cars as they did for the corresponding quarter of 1915, more psychology as well as more business acumen gets the scent of what is coming: a further threatened shortage of gasoline, and if not yet real, certainly threatened. If 650,000 new cars were added last year to the sum total running, it is no idle guess to state that a million will be added to the number in the current year of American prosperity: a single Detroit firm announces that it alone expects an output of 500,000 cars in 1916!

The most potent and obvious fact in the situation is that the consumption of gasoline will continue to expand in direct ratio with the expansion of the uses of the internal combustion engine, particularly the automobile, the auto-truck and tractor, and the motor-boat. There is some hope of finding limited substitutes for gasoline as fuel for internal-combustion engines, but these substitutes will most likely also be petroleum derivatives rather than of non-petroleum origin, such as alcohol. If the demand for gasoline or its equivalent continues to expand at its present rate, and if the supply of the raw product, its parent, is fixed within certain limits, there can be but one solution of the problem of how to meet the coming demand, and that is to increase the yield of the desired product from the crude-oil stock, or to increase the amount of oil that is consumed for refining by reducing the quantity consumed directly as fuel, which would be only a qualified relief under present conditions.

The expression "present conditions" is used advisedly, for but 15% of the crude-oil yield last year was made into gasoline, representing probably the maximum obtainable under current refinery methods, or the present state of the art. In other words, if there is to be an increase in the supply of gasoline it must come through improved methods of refining. With the above outline of the problem there are offered the following thoughts upon some of its possible solutions.

It was vaguely known in the chemistry of petroleum for more than fifty years that under certain conditions crude oil could be 'cracked' and made to yield a higher percentage of the more volatile products. To apply a process therefor and make available commercially a principle—if such could be done—was the mark set by many inventors and some few actual experimenters. 'Cracking,' in its simple analysis, means breaking up or disassociating by heat and pressure the molecules of the heavier hydrocarbons of crude oil and re-forming them into molecules of the lighter elements. The first important commercial advancement in this direction was gained in 1913 in a process brought out by W. M. Burton (U. S. Patent 1,049,667), wherein the distillates, or the secondary light products of the ordinary refinery, could be re-run in a still having the form of the common still, but working under about 75-lb. pressure. By this method the increase in yield of gasoline is pronounced. The process was at once taken up by the Standard Oil Co. of Indiana, and it is reported that 3,000,000 bbl. of gasoline was made with it last year; truly an encouraging advancement. But it was reserved for the year 1915 to produce what promises to be a greater achievement—that of Rittman. The eyes of five million users of internal-combustion engines are fixed upon it, asking whether this is a real star to which they can hitch their wagon, the allied petroleum products industries are scanning its possibilities, and the scientific world awaits confirmation of an indicated revolutionary discovery, proved by the commercial application of the new principle.

Briefly, what Rittman has done is to devise a practical method of applying the 'cracking' principle to its logical purpose; his method indicates the ability to convert any crude oil of whatever base (asphalt or paraffine, or mixed) or any product or any residue from such oils

from present refineries, into but three products:

1. Fixed gases, which can be used in the reduction process itself.

2. Fixed carbon in the form of coke, lampblack, etc., which always have a good market-value and a market not easily surfeited.

3. An oil, all of which can be made by repeated distillations into gasoline of any desired gravity, or by a different manipulation of the pressures and temperatures used, can be converted into the aromatic hydrocarbons, benzene, and toluene.

This discovery, preceded by years of elaborate experiments in the laboratory at Columbia University, in which the groundwork of the chemical principles involved was thoroughly worked out, has been demonstrated on a commercial scale with full-sized plants. What Rittman apparently has done is to go a step in advance of Burton, who had already achieved success, but upon radically different lines. Burton dealt with distillates, or intermediate products only, and with moderate pressures (75 lb.) with combined liquids and vapors. Working on the knowledge that chemical control was more easily obtained when dealing with vapors than with liquids, Rittman at once converted all his oil into vapor, and by adopting a vertical tube of relatively small diameter for the working appliance to permit of using high pressures and better heat-control, in place of the large horizontal still of ordinary form, there was thus given him, *ipso facto,* the medium for some radically different and improved results. This is proved by the fact that from the same apparatus there can be obtained, by different manipulation and by varying the conditions of heat and pressure, either the aromatic hydrocarbons, benzene, and toluene, used respectively in the dye and the explosives industries, or the sweet hydrocarbons such as gasoline. It is too early to predict the ultimate effect a wide adoption of the process will have upon the ramified markets of crude oil and its products. If it proves a commercial success—in all that the term implies—the volume of production possible from new Rittman plants can hardly influence the gasoline market for two years to come, for it takes time to build plants and to do the necessary experimentation with individual oils. If the Rittman process does not prove successful on large-scale operations, there does not appear in sight much other relief in the way of improved processes to extract a higher yield of gasoline from crude oil. Considering the fact that economists place so high a value on our reserves of crude oil as to maintain that their primary use should be limited for purposes and uses for which there are no substitutes in nature—as for instance, lubricants and refined derivatives—there must be a profound readjustment of the bases of things pertaining to oil in the next five years, if not sooner. For one thing, the burning of it under boilers in unrefined state to generate steam must stop.

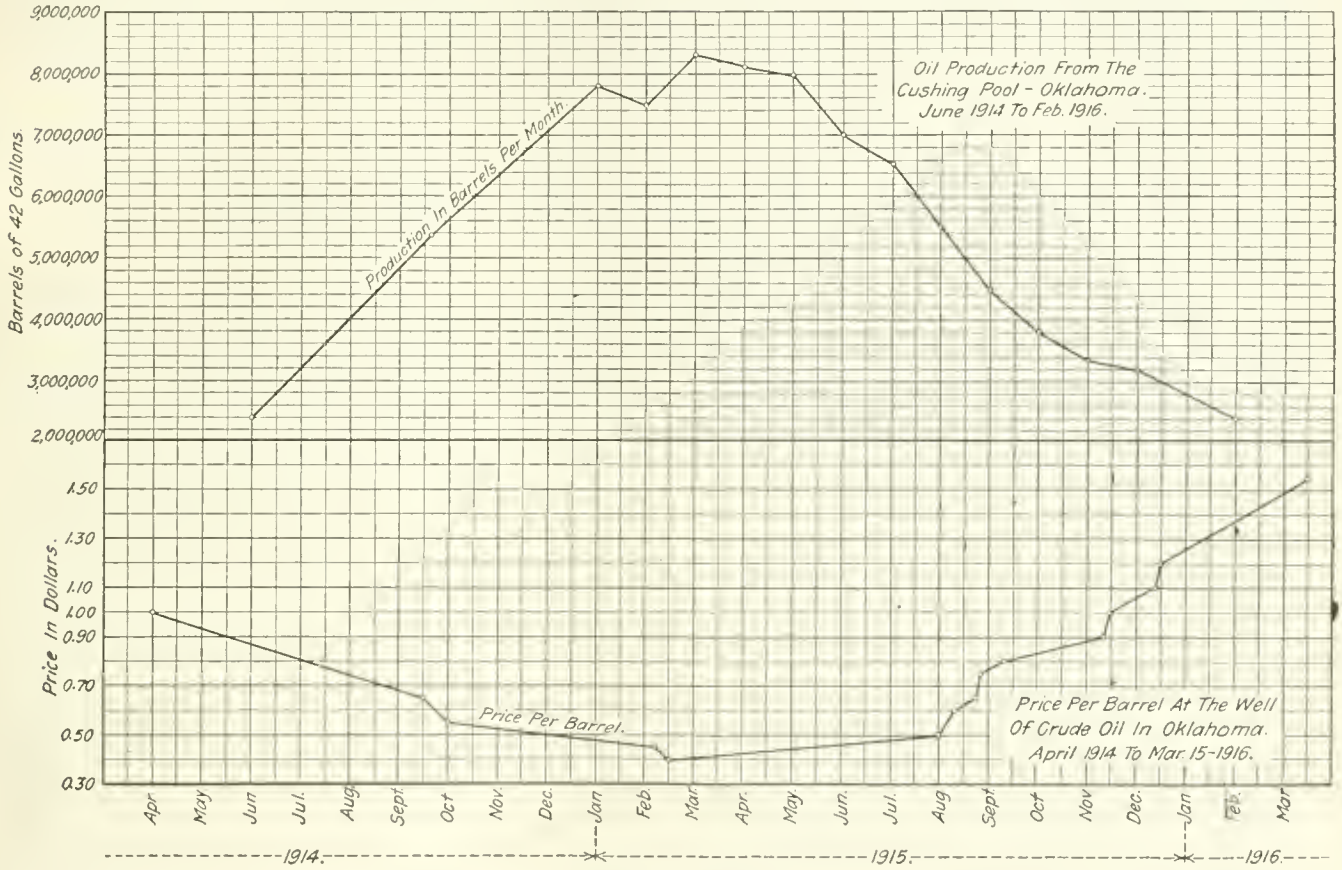


Fig. 2.

If the agitation over the price of gasoline yields no greater practical result than to call attention to the effect

of supply and demand upon the raw product—crude oil—and to the status of the refining art, it will have served a good purpose. If it will also bring out some fundamental facts about the oil business, as for instance (*a*) that its pursuit should occupy only those equipped with experience and highly efficient organization, (*b*) that the business is one requiring enormous amounts of capital, especially liquid capital that must be available on a moment's notice to throw into any new situation such as is created by the 'bringing-in' of a new oilfield, like Cushing, or the discovery of a new process that overnight will scrap the machinery of a plant covering 100 acres, (*c*) that the risks involved are more hazardous than any other form of mining operation (of which it can be considered a part), and mining is looked upon by the business world as involving the superlative of all business risks—if some of these fundamentals are brought out by the gasoline discussion, important light for guidance will be thrown upon many related questions. To substantiate or illustrate the point that enormous capital is required to engage in the oil business in a particular region we have only to turn to two particular ventures here in California in the past five years. One is the history of the General Petroleum Company and the other that of the Shell Company. It has been regarded as axiomatic that it required $25,000 worth of capital to 'turn over' one barrel of oil per day, that is, to buy or produce one barrel per day, and transport, refine, market, and distribute the products therefrom. The records of these two enterprises are much to the point: one is of domestic origin and primarily represents the consolidation of prior local interests, having only local capital to finance its operations, and whose affairs are now in process of re-organization, while the other is a branch of the Royal Dutch-Shell combination operating in most of the world's oilfields and having unlimited capital on which to draw. Data are not available to fix the sum of the first company's investment, but the latter is reputed to have expended thus far $30,000,000 to handle 10,000 bbl. per day production of the 250,000 bbl. currently produced each day in California, and has not yet concluded the capital expenditures necessary to put itself in the position to compete at all points in the Pacific Coast markets with the markets previously established.

In view of the above it would seem beside the question to rail against the undeniably large profits, as such, that lie in the oil business for those whom the public expects shall provide a gallon of gasoline at any hour of the day and every day in the year and at any consuming point on any continent. Acquired necessities impose obligations and for these obligations (and facilities) we must pay a good price whether or not we want to do so, so long as enormous sums, which the public does not provide, are required first to find at its own risk a commercial oil deposit, and then to produce, transport, refine and distribute the product. The point where artificially controlled conditions show nearest the surface is in the monopoly that goes with the pipe-lines that transport the crude oil from the well to the refinery, yet, as these are but one link in a longer chain, a breach at that point can hardly affect the problem in its larger aspect. If a conspiracy does exist to boost and maintain prices of gasoline, which statement the exhibit in Fig. 1 fails to substantiate, then the Standard Oil, which, as reported, refines 60% of our gasoline, emerges in the preliminary report of the Federal Trades Commission with the record of supplying the same, considering large averages over the whole of the country, at from ¼ to ½ cent under what the consumer pays the independent. Counting the experience, capital, and organization of the Standard, this is surprising mainly to those who lack familiarity with the subject. In saying this we hold no brief for Standard Oil, for the term is used to represent a type of operations rather than a specific business organization.

Canadian Mineral Products at the Panama-California Exposition

In installing the mineral and metallurgical exhibit in the Canadian building at the Exposition, at San Diego, several interesting additions have been made to the excellent collection that was displayed at the Panama-Pacific International Exposition, and which was described in our issue of March 6, 1915. Noteworthy among these is a new set of anodes, cathodes, and starting-sheets from the Consolidated Mining & Smelting Company's smelter, at Trail, B. C., which shows the latest developments in the refining of lead by electrolysis: a number of automobile and bicycle parts plated with cobalt, instead of the usual nickel, which is attracting a good deal of attention; samples of sheet, bar, and wire monel metal, and a 1⅜-inch bar of this metal, one end of which has been used for a tensile strength test—breaking at 93,100 lb. per square inch—the other sharpened like a soldering iron and heated to redness, without showing appreciable oxidation, and the bar bent double in the middle while cold, without showing the slightest injury; several specimens of gold ore from the new discoveries at Kowkash and Boston Creek, Ontario: and some ore, concentrate, part of a cathode showing deposited zinc, and a pig of electrolytic zinc, made by the Watts process at the works of the Electro Zinc Co., at Welland, Ontario. The Watts process differs from other electrolytic processes in that the dissolution of the concentrate and deposition of the zinc is carried on in the same vat at the same time.

Of the old material, the marbles and building and ornamental stones are in a better light and show to much better advantage than they did at San Francisco, and make a wonderfully imposing display. The rest of the material is arranged in much the same way as at San Francisco.

MINERAL PRODUCTION of Alaska in 1915 totaled $32,854,229, an increase of $13,788,563. Gold contributed $16,702,144 and copper $15,139,129.

THE BEGINNING OF A TUNGSTEN-MILL NEAR ELY.

A HAND-JIG WORKING ON TUNGSTEN ORE.

Tungsten Mining in the West

By P. B. McDonald

A TUNGSTEN boom has taken hold of the West. In Colorado, Arizona, Nevada, California, and Idaho, the hills are being prospected, not for the old favorites, gold, silver, or copper, but for those unfamiliar minerals, scheelite, hübnerite, ferberite, and wolframite. These minerals, which were scarcely heard about until recently, are being found in numerous districts where their presence had never been suspected. In quartz veins mixed with gold ore, in old dumps of abandoned silver mines, on claims that were staked years ago for other metallic products, the presence of tungsten is causing a rejuvenation of prospecting and small-scale mining. In some instances, people who had paid high prices for worthless claims years ago, in the expectation of winning the precious metals, are now finding that their claims are valuable for tungsten. In Colorado, where the principal tungsten-bearing mineral of Boulder county is ferberite, every dark-colored vein is staked eagerly in hope of its containing tungsten, often it is only an iron oxide. At many of the stores in the mining settlements of the West, testing-kits for tungsten prospectors and even 'tungsten-prospecting helmets,' or hats to be worn in the blistering deserts of these States, are being advertised in the show-windows. A great number of small shipments of tungsten concentrate are being made, many of them by express, to the steel-making firms and ore-buyers who are paying such high prices for the mineral. When required as a constituent of tool-steel, the high-grade concentrate is charged directly into the furnace with the molten iron, to emerge later in a proportion as high as 15% of the steel. Scheelite, the tungstate of lime, is said to be less desirable than ferberite, because it makes a pasty slag in the furnace, but this fact has seemed to make little practical difference in the marketing of the ore.

One reason for the great number of men who have taken up the search for tungsten is the comparatively simple nature of its geologic occurrence. The minerals are found, for the most part, in quartz veins in granite. Such a formation is one for which the prospector has always had a particular respect, and that is why many of the tungsten mines of today were once worked for silver or gold, on which occasions the 'heavy spar' of tungsten minerals probably interfered with concentration. The white or gray scheelite, it is true, is in places difficult to distinguish from the quartz that contains it. Tests for the presence of tungsten are not difficult to make; the simple kits sold to prospectors contain only hydrochloric acid (with perhaps 25% of nitric acid), a small stick of chemically pure tin, and several test-tubes. The mineral to be tested is dissolved in the acid and boiled for 20 minutes over a candle or lamp. A shaving of tin is added, and the solution turns blue if tungsten is present.

In the review of mining on another page is a letter written from Ely by Mr. Fred L. Miner of a tungsten excitement in eastern Nevada. This is typical of what is taking place at various places in the West. In the case of Ely, this old mining settlement is well able to supply all the materials for a genuine mining boom. The Snake range, near the Utah line, where the discoveries have been made over a large area, is the second range east of Ely. An automobile ride of three hours over moderately good roads across the sage-brush flats leads to the scene of activity. In the centre of things is the snow-covered summit of Mount Wheeler, the highest peak in Nevada, 13,058 ft. high. Along the western side of the range in particular—the side toward Ely—a number of camps have been established, several mills are being built, and many claims have been staked. Most of the showings are scheelite, in small seams and patches, contained in quartz veins that strike across the north-

south trend of the range. The scheelite varies from pearly-gray or white of almost the same shade as the quartz to yellow or salmon pink. Hübnerite is found at several of the principal prospects, in some instances in association with scheelite; in fact, crystals of the two have been found intertwined. The quartz veins vary up to several feet wide and carry from ½ to 3% of tungsten, with high-grade patches of 15 or 20%.

The United States Tungsten Co., which is controlled by officials of the Tonopah Mining Co. of Philadelphia, is operating the oldest tungsten mill in the region, a mile south of Mt. Wheeler. This mine was staked by Charles Gaby, a well-known prospector of Ely, 17 years ago. He concentrated the hübnerite in a small mill. But the cost of freight was so high and the demand for tungsten at that time so uncertain, that he became discouraged. Since then the mine has been operated at intervals, but people were inclined to laugh at this attempt to mine such an unheard-of mineral as the black coal-like hübnerite. Today a number of companies are operating in the Snake range and other mills are being built.

Another factor that contributes to the attraction of preparing tungsten for the market is the ease of concentrating it; in many cases this is done in hand-jigs of the Joplin type, but where water is plentiful power is employed. The heaviness of the tungsten minerals makes them easy to separate, so that no complicated chemical process is necessary. Care must be taken, particularly with scheelite, not to reduce it to slime, as this friable mineral makes a very floury mess. Grinding to 30-mesh is about as fine as is done.

A notable feature of such modern prospecting is the extensive use made of automobiles. The 50 or 100 miles that it is necessary to traverse in order to reach a new discovery is covered with ease and speed by a succession of motor-cars. Auto-trucks and traction-engines are employed to take supplies, machinery, and equipment to the mines. Gasoline engines are used to run mills, to hoist, and to compress air.

It is probable, of course, that the diligent efforts being made in many parts of the West to produce tungsten concentrate, and the consequent flood of small shipments to the consumers and buyers of it, will tend to depress the price somewhat. But the widening demand for high-speed tool-steel is bound to call for a much greater amount of tungsten than was the case formerly. While the price for the concentrate may drop to more moderate figures than have ruled recently, the margin of profit will still be sufficient to benefit many of the operations lately started.

LEAD production in the United States during 1915 was 615,253 tons, compared with 568,329 tons in 1914. It is estimated that of the 1915 output, the American Smelting & Refining Co. produced 48%, compared with 56% in 1914. The action of the Bunker Hill & Sullivan Co., in building its own smelter in the Coeur d'Alene, will further reduce the proportion of lead smelted by the A. S. & R. Co.

Concentration of Lead-Silver Ore at Kellogg

The following data are from the annual report of the Bunker Hill & Sullivan company for 1915, Stanly A. Easton in charge:

Mill worked, days	356
Ore milled, tons	454,636
Assay of feed, per cent of lead	9.9106
Assay of feed, ounces of silver	3.8277
Contents of feed, tons of lead	45,199
Tons of concentrate	59,901
Average assay of concentrate, % of lead	62.2565
Average assay concentrate, oz. of silver	21.6738
Contents of concentrate, tons of lead	37,292
Extraction, % of lead	82.52
Contents of feed, oz. of silver	1,740,217
Contents of concentrate, oz. of silver	1,298,284
Extraction, % of silver	74.61
Value of feed	$5,144,653
Value of concentrate	$2,384,543
Economic extraction, %	46.35
Tons milled per 24 hours	1,277
Tons of concentrate produced per 24 hours	168
Tons of lead produced per 24 hours	104.75
Cost per ton milled	$0.421
Cost per ton of concentrate	$3.103

There was lost in tailing 17.48% of the lead and 25.39% of the silver, a total of 18.79%.

The approximate cost and selling value of the year's production was as follows:

	Cost		
	Tons	Cost	Amount
Concentrate	59,901.14	$18.40	$1,102,245.89
Shipping	59,901.14	0.289	17,338.35
Cost on cars at Kellogg			$1,119,584.24
Loss by fire-assay			56,752.62
10% lead-content			296,569.77
10% base-price			263,237.74
50% advance over base-price			243,189.08
Freight and treatment			901,081.61
Total lead charges			$1,760,830.82
5% silver discount			32,445.10
Total smelter charges			$1,793,275.92
Total cost			$2,912,860.16

	Selling value		
Production	Quantity	Average price	Amount
Lead in pounds	74,584,741	$0.04733	$3,528,899.17
Silver in ounces	1,298,284.22	0.49983	648,920.03
Total value			$4,177,819.29
Less cost			2,912,860.16
Profit			$1,264,959.04
Kellogg cost per pound of lead			$ 0.0150
Smelter cost per pound of lead			0.0240
Total cost per pound of lead			$ 0.0390

SLATE output of the United States in 1915 was valued at $4,958,515.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

PURE POTASH amounting to 25 lb. is contained in 2000 lb. of dried banana stalks, a ratio of 1:80.

BLUE-PRINT paper is likely to advance materially in price. The prussiate of potash that has been used to make this product was obtained exclusively in Germany. The price of the paper itself is advancing also.

FOR EMERGENCY PUMPS in mines, when sand in the water is likely to be troublesome, centrifugal pumps are preferred to electric plunger types. The ability to pump mud or grit is more valuable in such cases than added efficiency.

METAL MINES of the United States in 1914 employed 158,115 men, of which number 559 were killed, or 3.54 per 1000. All mines, including coal and quarries, employed 1,009,236, of whom 3193 were killed, equal to 3.16 per 1000.

TUNGSTEN, as an element in high-speed tool-steel, is used in proportions as high as 27%, but the usual range is from 6 to 15%. When 5 or 6% of chromium is also used, an effective combination is secured. Tungsten-steel is employed also to some extent for saws, valves, and automobile parts.

AIR in mines should not contain above 1.25% carbon dioxide. Miners show symptoms of distress when 3 to 4% is present, violent symptoms at 7 to 8%, great distress at 10%, cerebral symptoms and unconsciousness at 12 to 15%, and death after exposure for several hours to 25% of the gas.

WATER diverted from Niagara Falls for power purposes totals 575,000 hp., of which 390,000 hp. is used in the United States. Some of the electric-furnace products are ferro-silicon, ferro-chromium, tungsten-vanadium-molybdenum alloys, ferro-titanium, silicon-metal, aluminum, abrasives, calcium carbide, and artificial graphite. The electro-chemical industry is another consumer, including the generation of nitrogen.

RAILROADS in South America are as follows in kilometres (⅔ mile):

Republic	Kilometres	Republic	Kilometres
Argentina	33,500	Colombia	1,200
Brazil	26,000	Venezuela	950
Chile	9,000	Ecuador	750
Peru	2,800	Paraguay	606
Uruguay	3,500	Guianas	300
Bolivia	1,900		

METALLIC MAGNESIUM is now being made in the United States. Previous to the War, it was imported chiefly from Germany. It is used as an alloy with aluminum, and for 'seavenging' other alloys by reason of its avidity for oxygen and nitrogen. Its easy inflammability and high degree of combustion make it valuable for flash-lights and military purposes. High prices and secrecy, resulting in sales under other names, have marked the trade in this as in other minor metals.

PUMPING COSTS at the Old Dominion mine, Globe, Arizona, during the first six months of 1915 were abnormally high, by reason of unusual rushes of water from the porous formations around the mine. Water to the amount of 6,750,000 tons was lifted an average of 1200 ft. The tons of ore raised in that period was 99,000 or 68 tons of water per ton of ore, certainly a high figure. In fact, the pumping expense was 29% of the total mining cost, although all conditions at that time were abnormal.

OIL in some form distributed over pools of water effectively controls mosquito nuisance. Kerosene spreads well, but is easily driven by wind; crude oil lasts better, but breaks-up into patches; stove distillates are better than the former two, but are not thoroughly satisfactory. About the best oil is a fuel-oil of 27° B., which spreads well, has good lasting qualities, and is amenable to the ordinary knapsack spray-pump. Another good oil is a mixture of crude, 12 to 18°, and kerosene about 40°: equal parts, or one of kerosene to three of crude, approximating 28° B.

COMPRESSED-AIR introduced in the bottom of a pipe under water, for the purpose of an air-lift, should be distributed through the water of the discharge-pipe in bubbles as small as possible, instead of in unbroken masses. These bubbles rise and spread through the water, with the result that the column of mixed air and water in the discharge-pipe becomes specifically lighter than the solid water outside. This produces the discharge to surface. The point is that after compressed air is discharged into the water of an air-lift, it has no more effect as to lifting the water by pressure or 'blowing,' and the subsequent movement of the column is due entirely to gravity. The reason, of course, for requiring the air to be compressed to a high pressure is to enable it to discharge at the required depth of water.

MINING METHODS should be safe as well as effective. The room-and-pillar method has the highest rate of men killed per 1000 employed, namely, 5.75. Over-hand stoping in wide veins is next most dangerous, with 5.25, while the rate of the caving system is about 5, and that of over-hand stoping in narrow veins 4.75. Open-cut mining with steam-shovel has but 2.5 men killed per 1000 employed. The caving system, it is interesting to note, has an insignificant number killed by accidents from explosives, and has a less number killed by falls of rock than other wide-vein methods. Minor injuries are in about the relative proportions, with the caving method showing to even better advantage, having a total less than any of the other systems except the open-cut methods.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

CONDITIONS IN THE ZINC REGION DURING APRIL.

Production and sales of all classes of ore, including zinc, lead, and iron pyrite in the Wisconsin field during April broke all records for any month, and prior to 1904 is as great as the output covering the entire production for a year. The various districts show ample illustration of expansion from every point of view. Bad weather in the first two weeks of the month, and resulting bad roads, handicapped outlying producers considerably. Sporadic strikes at scattered points disconcerted producers for short periods, but whenever possible an amicable agreement was quickly made. There is a shortage of miners and laborers in every centre, and 1000 men can be placed in well-paid positions on short notice. One reason for this is found in the fact that throughout the region are excellent farm and dairy lands, and many farmers who take positions in the mines during the winter months turn their attention to their fields as soon as fair weather permits. Steam and gasoline plants have been superseded here by electrically-driven machinery. The current is supplied by two concerns, one at Mineral Point, Wisconsin, known as the Mineral Point Public Service Corporation, and the other at Galena, Illinois, known as the Inter-State Power Co., both operating under exclusive franchises prescribing the areas in which each shall be entitled to legal control. The north half of the field is dependent for power on the former, while the latter supplies all the centres of the southern half. The Inter-State Power Co. is now giving much better service. The completion of a number of new modern power and milling plants during the month brought to light properties destined to compare favorably in output with many of the regulars famous as zinc-ore producers. Prospecting was greatly stimulated in the southern areas, where scores of leases have been languishing for want of ready service by drilling outfits. More than a score of new Keystone drills were brought into the field for custom service. Encouragement was afforded producers in the leading centres by the closing of contracts for the construction of additional railway facilities, while a hard macadam road between Benton and New Diggings will give miners at all seasons of the year ready communication with markets. The introduction of electric-power shovels investigated by leading operators during the month and approved of for service in the zinc mines here should contribute considerably to an increase in ore recovery, as shovelers of all classes employed in Wisconsin mines have been scarce, and nearly all strikes occurring in the past three months find shovelers the first to walk-out. One type of machine found suitable can do the work of 20 shovelers, with only two attendants.

April opened with top-grade blende at $115 per ton, from which it advanced to $120 and $125 during the weeks of April 9 and 16. During the next two weeks the market eased off $5 per ton each week, and the month closed with the market steady at the same price which prevailed at the beginning. At several places milling companies were organized for the purpose of re-treating tailing-piles with fair zinc-content. Increased dividends were paid.

Deliveries of ore in April were 46,396,000 lb. of zinc, 1,111,660 lb. of lead, and 6,772,300 lb. of pyrite. Sales to works amounted to 23,198 tons.

CRIPPLE CREEK, COLORADO

DRAINAGE PROGRESS. GOLD OUTPUT. NOTES.

During April the Cripple Creek drainage tunnel was advanced a distance of 235 ft. The heading is now 500 ft. east of the main Elkton shaft, and is still within Elkton territory. Last week a new water-course was cut by the tunnel, and for a few days the flow of water from the portal was increased. At the present time there is reported to be more than 15,000 gal. per minute flowing from the portal. The connection has been made between the bottom of the Elkton shaft and the drainage-tunnel. The work of timbering the intervening space is about finished, and soon the rock broken in the adit heading will be hoisted to the surface through the Elkton shaft.

Production from the Cripple Creek district for April as reported by the mills and smelters is as follows:

Golden Cycle, Colorado City	40,000	$17.00	$680,000
Portland, Colorado Springs	11,500	20.00	230,000
Portland, Victor mill, Cripple Creek	17,500	2.72	47,600
Portland, Independence mill, Cripple Creek	12,400	2.60	32,240
Isabella, Cripple Creek	1,000	2.50	2,500
Caley-Jerry Johnson, Cripple Creek	825	4.60	3,795
Worcester	200	3.50	700
Smelters, Denver and Pueblo	4,050	55.00	222,750
	87,475	$13.94	$1,219,585

The Worcester mill appears in the table for the first time as a treatment plant. It is situated on the south-western slope of Bull hill, on the estate of the Ruby company. The mill will treat mine and dump ores from the Ruby mine.

Frank Vetter, alderman of Cripple Creek, with his associates, is forming a new company to be known as the Albert-Beacon Gold Mining Co., with a capital of $250,000. The new company will operate the Prince Albert Beacon and Eureka claims under lease, with bond to purchase.

It is reported that the El Paso company contemplates the erection in the near future of a mill using a flotation process.

TUCSON, ARIZONA

SMELTING, TUNGSTEN, AND MEXICAN CAPITAL.

The Sasco smelter, owned by the American Smelting & Refining Co. is beginning work on a fairly large scale. Last week the second furnace was blown-in. Converting matte and pouring blister copper is in regular operation. About 600 tons of ore per day is being received from several properties, among which are the Christmas with 250 tons, Silver Bell, 150 tons; Bush-Baxter, 80 tons; and Imperial, 50 tons. E. G. Bush's mine at Twin Buttes is also to be a heavy shipper, and the Silver Bell it is hoped will soon double its output. This speaks well for the local plant, and shows how development is shaping in this Pima county district.

A great deal of excitement continues in the tungsten areas of this State, notably the Dragoon and Las Guijas mountains. Both of these centres look like tent cities. Nearly all prospectors have left the search for gold for tungsten veins and placers. Work by the American & National Tungsten Co. at Las Guijas goes on. The writer thinks that the low and un-

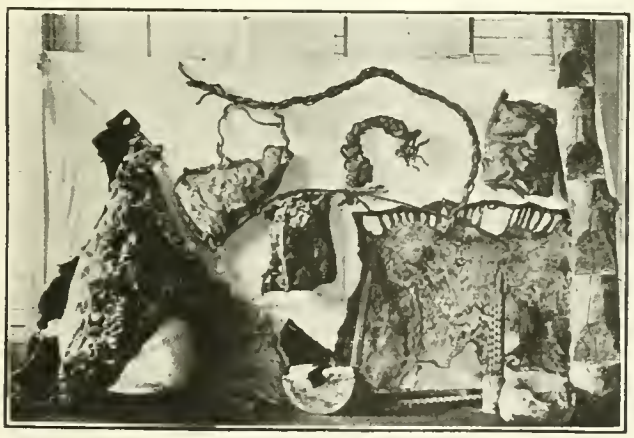
attractive wages are conducive to inefficient work. It is estimated that during the past few months no less than $60,000 of tungsten float has been picked up on the surface in the Las Guijas vicinity.

The Southern Belle group of claims, situated at Campo Bonito, Pinal county, which was owned by the Fellows estate of New York, has recently been taken over on an option by a brother and two uncles of the late Francisco Madero, once president of Mexico. They are Emilio, Jose G., and Benj. Madero. The price paid for the property is understood to be $100,000. The ground was formerly considered a gold mine with tungsten as a by-product, but since tungsten has become so valuable it is now to be worked for the tungsten content. The principal ore is scheelite. The Maderos, who are reputed to be wealthy, expect to enter the mining field extensively, and in addition to the investment of their own funds, which at present are somewhat tied up in Mexico, owing to the revolution, they have strong backing in New York. As the Southern Belle property is more fully developed and conditions warrant, a new concentrating mill will be erected and work continued on a large scale. Emilio Madero will have the management. He is a graduate of the Boston Institute of Technology. An office is expected to be established soon in Tucson: although at present El Paso is headquarters for the Maderos.

SANTA RITA, NEW MEXICO

Old Mining Methods at Chino.

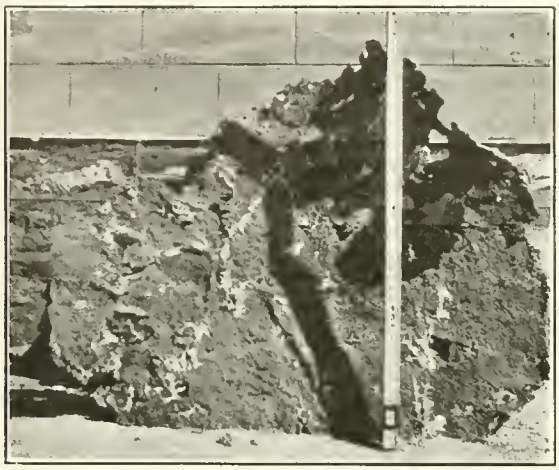
Evolution of mining methods from the old antiquated operations of Spanish days to the modern economical systems employed at mines today, is well illustrated by the recent discovery by the Chino Copper Co. in its mine at Santa Rita, of the old apparatus or a portion of the old appliances used by the miners in the early part of the 18th and 19th centuries. The majority of the old workings are in what is locally known as the 'south workings' of the Chino company. Here the



OLD LADDER AND ORE-BAGS AT THE CHINO MINE.

Spaniards had mined for over a hundred years, going to a depth of 150 to 200 ft. It has been possible for the present company to recover among other relics several sets of mine timbers still in a good state of preservation. The timber was chiefly juniper, cut to lengths of about 4 ft.; this, for their main adit, while bear grass was used for packing.

In the accompanying photograph may be seen the style of 'chicken' ladders made of juniper logs 6 to 8 in. diam. and 10 ft. long, with notches spaced 8 in. apart for foot-rests. These poles or ladders were set upright or at a slight angle held in place by thongs of deer hide, binding them securely to platforms just large enough to permit a man landing, and to give support to another ladder of similar dimensions, thus making a very hazardous means of communication from one level to another. These ladders were used principally in the underground workings. The main shaft was supplied with a wooden pulley and windlass. A portion of the former, still intact, is on exhibit among the other relics in the company's offices at Santa Rita. Here also may be seen numerous buffalo or deer-hide bags; in many instances the hair still adhering to the outside. They were used in carrying ore from one level to another, and the larger ones for hoisting ore in the main shaft. All were laced with thongs of hide, and are still remarkably well preserved. The poor equipment of those days



NATIVE COPPER FROM THE CHINO MINE.

naturally limited mining operations, and only high-grade ore or native copper itself could be profitably mined. This was shipped by burros to Old Mexico and the sea-coast several hundred miles distant. However, a good deal of native copper was obtained at that time, and is still found by the present company, as is evidenced by the picture showing a slab of native copper recently taken from these workings.

The vicissitudes and trials of modern mine operators in the United States, great and annoying as they undoubtedly are, still have some compensation in the fact that they are not molested by the warring red-men who overran New Mexico during the Spanish régime, making mining in this region a still more hazardous undertaking. In order to safeguard their property the Spaniards accordingly built an adobe fort, triangular in shape, covering several acres in extent, with round towers at each corner. Built of adobe bricks, the walls of the last remaining fort are 4 ft. thick, with loop-holes every 6 ft. or so in its face. It stands as the last memorial above ground of the original miners of Santa Rita, New Mexico.

At the present time the Chino Copper Co. is operating 10 steam-shovels, employing 1000 men and handling 8000 cu. yd. of material per day, a tremendous advancement in mine operations as compared with the original efforts of the early miners.

ELY, NEVADA

Tungsten Mining in White Pine County.

The Snake range, in the eastern part of White Pine county, for a length of 70 miles, is rapidly developing into one of the greatest tungsten-producing belts in the United States. Many companies are operating on an extensive scale, with several mills in operation and others under construction. Prospectors are in plenty from one end to the other of the proved tungsten zone, practically all of them having found good deposits of hübnerite or scheelite. Each discovery increases the excitement and interest around Ely, and causes a new rush of people eager to get in on 'ground-floor' locations.

The Snake range is not alone as a tungsten field, further ex-

citement being reported recently by reason of discoveries of ferberite in the Shell range, 18 miles from Ely. The ensuing exodus to the new district took practically every automobile out of town, and many people went by wagon and other horse conveyances. This discovery was made by R. F. Vevia, with whom D. F. Paine is equally interested. The former found the vein by tracing float ore, which led him to an old shaft that had been sunk years ago in a search for silver. Specimens that he brought to Ely return from 20 to 40% tungstic acid. Vevia thinks that there is at least $5000 worth of ore on the old dump. The vein is 20 in. wide, and yields mineral wherever prospected. The importance of the discovery is the fact that it demonstrates that tungsten ores exist in the Shell Creek range, which will now receive thorough prospecting.

While the most important discoveries have been made on the west slope of the Snake range, good deposits are also found on the east side. A number of old properties that were formerly worked for silver are now found to contain tungsten ores, which will result in their re-opening. Because of its more extensive development, the west side of the Snake range is naturally the centre of interest, and a good production is being made by a number of properties. New mills are in course of construction by several companies, and the great activity prevails all along the range.

The United States Tungsten Corporation is the largest operator at the present time, but others are coming along at a rapid pace.

The Independent Tungsten company, organized by A. D. Meyers, Charles Gaby, William Stewart, K. C. Davis, and Duncan MacVichie, is employing about 50 men on development and construction on a 30-ton mill. A large compressor-plant is being installed at No. 1 adit for machine-drills. The mine has a strong shoot of scheelite in a number of places. The company will become one of the most important producers along the range. Numerous smaller operators are also working in this district, which is known as Scheelite.

Farther south, 1½ miles from the U. S. Tungsten Corporation is the Consolidated Tungsten Co., which was organized by McGill people, and has 20 lode claims and 10 placers. They are now constructing a 30-ton mill, part of the machinery having been shipped to the property. The Big Four vein is opening especially well, ore being traced on the surface for 400 ft. Some of the workings show so much hübnerite that they resemble a coal mine, with the black ore. The streak of high-grade is 3 ft. wide in a vein that is from 7 to 11 ft. wide. Large bodies of good ore have also been opened in the Gem and Gem Extension claims. The Doseoaris vein is in another promising area. These claims are in Williams creek, and an ample supply of water is available. In this neighborhood, as elsewhere along the range, are a number of other excellent properties that are still in the prospect stage, but giving promise as future producers. The formation here is granite and quartzite, the veins occurring in both formations.

The Minerva district, 14 miles south of Williams creek, is apparently one of the best that has yet been opened. The veins are intrusions in limestone, and the ore a pearl-gray scheelite.

The Nevada Scheelite Co., composed of Salt Lake City people, and managed by William Stewart of Ely, has 20 claims under bond and lease from Jasper M. Fox, C. T. Millick, and A. G. Millick, for $300,000. They also have 5 other claims held by location. The Scheelite Chief claim, just above the newly established camp, has one of the best developments along the range, and is of bonanza quality. Many years ago it was worked for silver, but was finally abandoned without the presence of tungsten ore being detected. The vein shows a continuous outcrop of 1200 ft. At the main workings the ore-shoot has been proved for 80 ft., averaging 9 ft. in width, from which four cross-section samplings showed an average at surface of 2.85% tungstic acid. The owners are mining and sacking ore from a high-grade streak 2½ to 3 ft. wide, that will yield 1.5%. Some of the selected ore contains 50 per cent.

The Oriole vein, paralleling the Scheelite Chief about 1500 ft. to the north, can be traced for 3500 ft., and is producing some fine ore. The vein varies from 1 to 9 ft. in width, and samples along 70 ft., for an average width of 7 ft., show an average of 1.91% tungstic acid. Some high-grade shoots have been cut and a large quantity of ore is being sacked.

One of the other strong veins of the group is the Everett, at the north end of the property. It outcrops prominently, and can be traced for 4500 ft. Samples in a 65-ft. shaft, across 5½ ft. of ore, give 1.12%, and a 12-ft. sample, 50 ft. west of the shaft, gave 3.60%. A small shoot paralleling the main vein is practically all high-grade ore, and five sacks that were taken from here and hand panned yielded 200 lb. of 64% concentrate.

Arnold Millick, W. S. Elliott, J. Briggane, and others have a good group of claims north of Minerva, on which development is now under way, on veins from 4 to 10 ft. wide, that show fair quantities of scheelite.

Clyde Tilford, Sheriff Crain, T. Barton, and D. Millick also have some promising claims in this neighborhood, on which development is in progress with good results.

There are numerous other properties being prospected and developed along this portion of the range, as well as elsewhere, and many of them will soon gain prominence as producers of tungsten ore, which is making fortunes for many. This is undoubtedly the greatest poor man's opportunity that has ever come to light in Nevada, for the ores, by a little sorting, will easily average $100 or better per ton at surface. It is unusually easy mining, and if it was gold ore of equal value it would be spectacular, and the excitement would be many times greater than that which now exists. Men who are unable to secure locations can find desirable opportunity for leasing, and present indications are that several hundred lessees will be at work along the range during the coming summer. The roads which were blocked with snow for several months during the winter are now in first-class condition, and are lined with teams and auto-trucks hauling in supplies, and autos loaded with prospectors, operators, and investors.

FAIRBANKS, ALASKA

PROGRESS IN MINING AND TREATING THE TUNGSTEN ORE, SCHEELITE.

While tungsten mining in this district is in its infancy, the little that has been accomplished and possibilites are of interest. Naturally there has been no metallurgical skill tried, the main idea being to produce concentrate as soon as possible. However, what has been done is creditable to those concerned, and one mill is to be altered to give a better extraction.

There are but two properties producing tungsten ore at present, in both cases the product being scheelite. These are the Johnson and Ewers property at the extreme head of Gilmore creek, and the Ott Mining Co. of upper Fairbanks creek.

The former ground was prospected for and located by Albert Johnson in the summer of 1915, scheelite being found in the placer sands of Gilmore creek, and traced to its source. The property was worked through the winter as far as weather permitted, and 50 ft. of shaft and 30 ft. of drift supplied the 50 to 60 tons of ore that has been concentrated so far. The inclement weather prevailing during the past winter, combined with the fact that the property is on a high ridge, rendered operations most difficult. For days it was impossible to leave the cabin, and the partners deserve much credit for accomplishing as much as they did, handling all rock hoisted with a windlass. The vein is in a well-defined fissure in limestone, and the ore is sometimes 4 ft. wide. It occurs in narrow, sharply-dipping shoots or lenses from a few feet to 20 ft. long. Surface prospecting has shown the ore to outcrop for a fair distance, so that owners seem justified in their

belief that considerable ore can be mined this summer. The ore is sacked and hauled by team to Gilmore station, thence it is shipped to Chena by the Tanana Valley railroad. The Chena custom mill has lain idle for several years, but Johnson and Ewers made arrangements to put in a boiler and get the mill in order again. Besides this expense, it is understood that a milling charge of $8 per ton is paid. The owners calculate that it costs them between $20 and $25 per ton to haul and concentrate the ore. The mill is a 10-stamp Joshua Hendy type, but only one battery is in use. After going through the crusher and into the bin, the ore is stamped and passed over plates to the classifying cone. It is not known to what size the ore is crushed. The sand goes to a Deister sand-table, and the overflow to two Deister slime-tables. This completes the treatment, the same arrangement being used as that originally installed to deal with the gold ores of the district. There is practically no gold in the ore. So far, the extraction is uncertain, as the final drying and weighing of concentrate has not been completed. The tailing shows a content of 0.5% tungstic oxide, while the owners think from the preliminary recovery that the ore will average between 5 and 6%. This would indicate a rather high recovery, although it is not known if the tailing sample was properly taken and settled. At present the concentrate assays 63%, and is shipped in 20-lb. sacks by parcel post. After navigation opens, it will go by express by the water route. It is probable that every effort will be made this summer to erect a mill on the property and save the high transportation charges.

The discovery of scheelite on the lease worked by the Ott Mining Co. was rather a surprise to lessees and owners alike, the property being hitherto worked for gold alone. The tungsten ore did not show in the surface workings, and was found by driving. It has persisted so far for 60 ft. in the drift, and is still in the face and floor, but only for 5 ft. above the drift, where the gold ore alone is found. Further prospecting at depth will immediately be done to determine the extent of the deposit. The vein is in a well-defined fissure in a blocky schist, probably of igneous origin. The vein varies from 8 to 24 in. in width, the best value in tungsten being found in a layer comprising about half the vein on the footwall. The other half carries the gold, which is rather high in some parts of the vein so far opened. No attempt was made to keep the gold ore separate in the first mill-run of 55 tons. It was considered that of this, from 15 to 20 tons contained most of the tungsten, the rest having the bulk of the gold. The property has a small steam hoist, and is situated about 400 yards up the hillside from the Heilig custom mill, where the ore is now treated. The ground is leased from Hess, Geis and Thompson. The vein is a parallel one to the Mispah, which is worked by the owners and has produced close to $10,000 in gold during the last 12 months with 2 to 3 men working. When the tungsten ore was opened, neither the Gilmore and Stevens stamp-mill nor the Heilig custom mill had machines for concentrating it. Immediate plans were made by C. E. Heilig of the latter mill to handle same, and by the time the 55 tons was mined, the mill was ready. A small addition was put on the mill, and a Monarch concentrator built by the Seattle Construction & Drydock Co. was installed. The table had been in use a short time at the Furstenau mill at the head of the creek, and had been idle for several years. As the inclement weather made it impossible to grade for the table, so the pulp could be put on the table by gravity, a bucket-elevator was constructed to lift the pulp below the plates. A small independent engine was put in to drive the table, but this failing at the last moment, it was necessary to belt to the main mill engine. Better results could have been obtained with the independent engine, a constant speed being possible. The large Jones gyratory breaker in the mill causes at times a variation in the speed of the mill engine that is not conducive to best results with the table. The ore is crushed in a Huntington mill, working at 100 r.p.m., with a 40-mesh slot-screen. From 15 to 20 tons is milled per day. The work of the table was entirely satisfactory and produced a clean high-grade concentrate. At times the entire space between the carrying riffles was covered by a pure white concentrate. The middlings were saved separately, and put over the table again, with different grade and stroke. Regrinding with classification to sand and slime-tables would have resulted undoubtedly in a better extraction, but the means were not at hand. For unit concentration with classification, probably no other table could have done any better under the circumstances. The Huntington mill, comparing the products of the tables at Chena and at the Heilig mill, undoubtedly produces less slime. At that, the tailing has been banked at the latter mill, and will be tested on a canvas plant during the summer. If the ore developed warrants the outlay, rolls, jigs, and a slime-table will be put in later. From the 15 to 20 tons of tungsten ore, 1200 lb. of 62.5% concentrate was extracted. This has been sent by parcel-post in 20-lb. sacks to the Crucible Steel Co. It is understood that the price paid on a basis of 60% was $60 per unit f.o.b. Fairbanks. Besides the concentrate, the mill run netted $418 in gold. The next shipment will go by water.

The Johnson-Ewers property is the only one found so far by prospecting a tungsten trace, although in several other places (four, to be exact) that the writer, L. M. Drury, knows of, strong tungsten traces are known. As soon as the snow goes and the ground thaws enough to make rapid work possible, many prospectors will start to find the source of the placer scheelite. The head of Cleary creek shows a placer sand of about half scheelite, while on another placer claim on another creek, a placer sand is found that is about half scheelite and half magnetite. At the present price, probably several thousand dollars worth of scheelite has been wasted, with only a volume of curses to speed it on its way for clogging riffles and making clean-ups difficult for the placer miner. While no notable deposits may be found, it is more than a sporting chance that the Fairbanks district will make a name for itself as a tungsten producer.

TORONTO, ONTARIO

HUGE CONSOLIDATION AT PORCUPINE.

A merger has been arranged including the Hollinger, Acme, and Millerton mining companies and claim 13,147 of the Canadian Mining & Finance Co., under the title of the Hollinger Consolidated Mines, Limited, with a nominal capital of $25,000,000 in $5 shares. Of this number, 200,000 shares will remain in the treasury and the balance will be distributed as follows: Hollinger shareholders, 2,400,000; Acme, 2,100,000; Millerton, 200,000, and Canadian Mining & Finance Co., 100,000 shares. A detailed report has been issued by P. A. Robbins, general manager of the Hollinger, giving the reasons for the consolidation, which has been contemplated for five years. The centralization of the plant and the development of underground workings have been carried on with a view to an ultimate merger, and as a point has been reached where comparative valuations of the properties can be made, and the interests of all benefited by amalgamation, the project has become feasible. Mr. Robbins estimates the assets of the Hollinger as approximately equal in value to the combined assets of the other companies embraced in the merger, and anticipates that with the extension of the Hollinger mill and the completion of the central shaft, the dividend rate will probably be increased even with a reduction in the value of ore treated. Dealing with the allowance for ore at depths below those already reached by development in the Hollinger and Acme properties, he estimates that on the basis of a depth of 800 ft., there are 5,594,570 tons of ore with a gross value of $18,196,390. On the assumption that the veins persist to a depth of 1400 ft., as some of them have been proved to do, there is 10,130,000 tons worth $81,492,000.

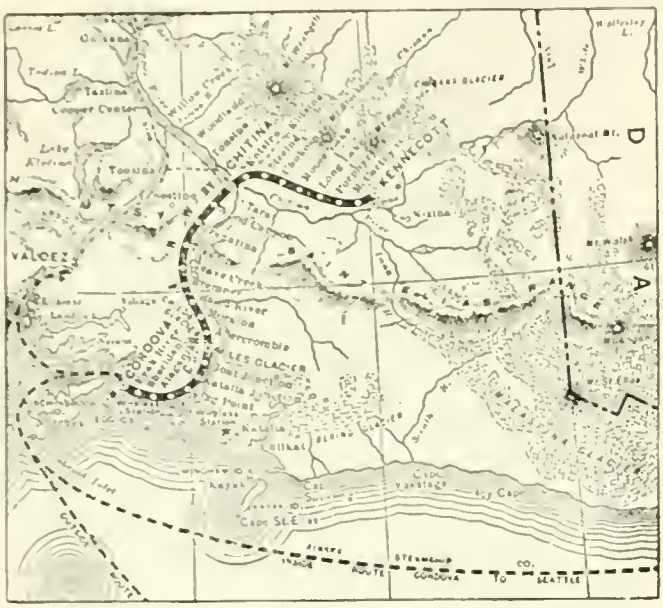
THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Cordova

Movement of copper from Alaska to 'The States' in the eight months ended February 29 was 69,062,394 lb., valued at



MAP SHOWING ROUTE TO KENNECOTT, ALASKA.

$13,597,148, compared with 21,240,265 lb., worth $2,609,650 in the same period of 1914-'15. The Bonanza and Beatson mines of the Kennecott company supplied most of this metal.

Juneau

The April output of the Alaska Gastineau mine was 165,930 tons of 94-cent ore, against 162,796 tons worth $1.03 in March. The tailing loss was 19.8c. per ton, and recovery 78.71%, a slight decrease and increase respectively. The following telegram was sent by the general manager, B. L. Thane, to New York:

"Expect over-run will bring heads up equal to last month. During first 23 days ore came from low-grade slate zone west of the shaft. Last seven days we began to add some tonnage of ore east of the shaft. During this period 40,000 tons was milled, averaging $1.40. Condition of stopes east of the shaft shows great improvement, and I shall be able to resume delivery of ore from No. 2 east No. 5 level, and from new stopes opened east on No. 6 and 7 levels. Grade of ore should improve during the entire month of May, and show marked improvement throughout June. Tonnage maintained. Expect will be about 6000 tons per day until about the middle of June, when new stopes east of the shaft should be in good condition to deliver their proper proportion of ore so that tonnage can be thereafter increased."

Valdez

New York capital has bonded the Pandora copper property on Knights' island, six hours by boat, from Burns, Jordan, and Welch, for $650,000. The ground is said to be of considerable promise and will be thoroughly exploited.

ARIZONA

Cochise County

Bisbee mines continue to produce an enormous quantity of copper. The smelters at Douglas cannot treat all the ore offered from their own and outside mines. This is hard on small producers and lessees, of whom there are so many. Additions to the Calumet & Arizona plant will relieve the situation later on. The Copper Queen smelter produced 18,000,000 in April. During the first quarter of the current year the Shattuck shipped 37,381 tons of copper ore and 3544 tons of lead ore, yielding 4,682,691 lb. copper, 1,481,387 lb. lead, 1538 oz. gold, and 89,695 oz. silver. The net cost of copper was 6.44c. per pound. The profit was $781,380. Dividends absorbed $350,000.

Gila County

The Inspiration mill has been treating up to 15,900 tons per day, much in excess of the rated capacity. A telephone system with 200 instruments is being installed at the mine engineering office to be in touch with all parts of the property.

Mohave County

The next 90 days promise to be the most important in the history of the Oatman district. Depth seems to be necessary at this centre. It has been found that depths ranging between 300 and 600 ft. must be attained before persistent bodies of commercial ore may be expected. This condition is due to variations in geological and topographical elevations caused by the rapid and extensive erosion which has taken place in the very rugged and precipitous territory embraced within the district. To sink shafts to these depths and to do the requisite cross-cutting and driving to encounter orebodies requires much time and expense. Practically all of the operators have the 500 or 600 ft. point as their objective. Most of these properties were not able to begin development with machinery until late in 1915. In this district it usually requires three or four months to sink and complete a shaft 500 ft. deep. At this time a number of properties have reached their objective point in depth, and are now engaged in lateral work which may bring them into commercial ore in from 1 to 90 days. The properties to which this principally applies are the Oatman Gold Mining & Milling, Fessenden, Ivanhoe Consolidated, Boundary Cone, United Western, Black Range, Arizona Tom Reed, Lucky Boy, and Gold Range companies. The two last named are still sinking, but are nearing the 400-ft. point, and indications are such as to lead the operators to think that they will be justified in cross-cutting on their 400-ft. levels.

At the Golconda zinc mine the main shaft is down 1050 ft. in high-grade ore. Monthly development totals 1000 ft., and smelter shipments 1500 tons.

Yavapai County

The Tip Top Consolidated Mining Co. has been formed to operate the Tip Top mine which contains silver and tungsten ores, the latter of good grade. The property has an interesting history. Reserves are 20,000 tons of $23.50 ore in stopes, 1000 tons of $66.60 in place, and 20,000 tons of $21.50 on dumps, a total value of $966,600. Extensive development and a larger plant are contemplated. The president is C. W. Davis.

Pinal County

Ray Consolidated Copper Co. reports as follows for the first quarter of 1916:

Development, feet	14,202
Ore treated, tons	745,940
Average content, per cent	1.631
Copper from all sources, pounds	15,801,568
Cost, cents per pound	10.579
Average price received, cents per pound	24.598
Profit	$2,205,578
Dividend paid	789,302
Net surplus	$1,416,246

CALIFORNIA

Amador County

(Special Correspondence.)—An important mining deal, so far as this county is concerned, has just been closed here, the McIntire, Boyson, North Star, and South Keystone properties having been taken over by a strong company headed by W. Virges and A. Huth of Tacoma, Washington. With the exception of a 1000-ft. shaft on the North Star claim almost no development has been done on these mines, but the ground has favorable indications. The area adjoins the Keystone mine on the south, and is on what is known as the 'Amador Trail' between Sutter Creek and Amador City. As soon as the North Star shaft can be unwatered and put into proper condition, the intention is to start driving from the 600-ft. level to cut the South Keystone orebodies. The necessary machinery is to be installed without delay. The North Star shaft is well situated for quickly exploring the value of the combined properties. Charles H. Colpe is manager. The strenuous efforts of John A. McIntire of Sacramento for many years are chiefly responsible for the consolidation of these claims and interesting capital in their development. He was the owner of the McIntire claim, and is well versed in Mother Lode conditions. The opening of this ground may mean as much for the county as does the work contemplated at the old Eureka.

Sutter Creek, May 15.

At the Eureka mine at Sutter Creek a quantity of machinery and supplies are arriving. A small hoisting plant, to handle the sinking-pumps, is being erected. The superintendent, Walter Beam, is now living at the mine.

San Diego County

As the Panama-California Exposition is to remain open until the end of 1916, and as a number of exhibits have been transferred from the late Exposition at San Francisco, the Palace of Mines at San Diego is filling up and attracting more attention. The Nevada Mine Operators' Association is to arrange a display of minerals, also several California counties, and a good collection from Oatman, Arizona. The building is in charge of J. E. Babcock and A. E. Smith.

Inyo County

According to the *Owens Valley Herald* of Bishop, that place "is the centre of the biggest tungsten field in the United States." Six miles west of Bishop a new townsite is being laid out. Near-by the Tungsten Mines Co. and the Standard Tungsten Co., managed by L. L. Stevens and A. J. Clark, respectively, have developed extensive deposits of scheelite. The Tungsten is erecting a 75-ton and the Standard a 300-ton mill, the latter the largest in the country for tungsten ore. Other discoveries of tungsten are reported.

Sacramento County

The Natomas Company of California has sold in reclamation district 1000, three miles north of Sacramento, 1114 acres of land at $300 per acre to M. J. and A. J. Machado, E. A. and A. R. Meister, and E. J. O'Brien of Sacramento, and D. H. Moulton of Chico.

Shasta County

The electric smelter of the Noble company at Heroult is producing 12 tons of ferro-manganese per day from one furnace. Another furnace will soon be charged. About 125 men are employed at the property.

Guggenheim interests have bonded two tracts of land near Redding, about 1000 acres, and is prospecting it by drilling in charge of E. A. Wiltsee. The El Oro Dredging Co. has bonded 160 acres on Clear creek.

Trinity County

On account of water troubles in its mine, the Globe Consolidated has temporarily closed its mine and mill. Hydraulicking continues in full force at Lagrange and Union Hill.

Tuolumne County

(Special Correspondence.)—The long adit being driven by the Springfield Tunnel & Development Co. to open the gravel-channels near Columbia, has reached what is known as the Buchanan channel, where rich gravel has been found. It will be several days before the centre of the channel is exposed. On the rim the gravel is about 4 ft. thick. Other ancient channels whose richness was proved by sinking

MINES BUILDING AT SAN DIEGO.

shafts will be opened from time to time as the work of driving the adit progresses. The position of general superintendent, made vacant a few days ago by the death of A. L. Horner, has passed to Joseph Cadenmartori, for several years in the company's employ.

Although the Dutch-Sweeney plant is one of the best and most complete in the county, improvements are still being made. The two Hardinge conical mills recently installed are giving satisfaction. Of the discoveries made in the mine since the present company acquired the property, probably the most promising is on the 1800-ft. level, where a large body of fine ore is being opened.

Sonora, May 6.

YUBA COUNTY

Title to 1619 acres of dredging ground in the Hammonton district is in dispute between the Yuba Investment Co. and the Yuba Consolidated Goldfields Co. in the Superior Court at Marysville. A large array of legal and mining talent is represented. Drill-holes yield from 4 to 30c. gold per cubic yard. For dredging purposes, J. K. O'Brien, the original owner of the land, considers it worth $15,000 per acre, but for agriculture only $30,000 for the lot.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—With silver rising resumption of work is promised at an early date on a number of old properties that have been dormant for years. Georgetown and Silver Plume are experiencing greater prosperity than since 1893. Every habitable house in both towns is at present occupied and sleeping accommodations are scarce. Several buildings at Georgetown are being re-modeled and made into rooming-houses. It is estimated that no less than 400 miners have been brought here during the last month to assist in mine development.

Idaho Springs, May 8.

GILPIN COUNTY

There is a scarcity of machine-men and single men at the mines of this county.

OURAY COUNTY

During March the Camp Bird mine made a profit of $43,709 from 1947 tons of ore.

TELLER COUNTY (CRIPPLE CREEK)

The postponed sale of the properties of the U. S. R. & R. Co. failed to receive a bid, with a minimum of $200,000. The Court has ordered at the next sale that the cash deposit of $50,000 remain as before, but withdraws any minimum.

Spencer Penrose of Colorado Springs, a bondholder of the U. S. R. & R. Co. since bought the properties for $100,000.

THE SAN JUAN REGION

Mining men are getting ready for a prosperous season in the San Juan mining centres. Prospecting, developing of producing mines, building mills, and constructing roads and trails will soon be on in full operation. The Durango smelter is already receiving a greatly increased quantity of ore from Silverton, Rico, Telluride, and other producing districts. Twenty-one empty freight cars were taken to Silverton one day last week to bring down ore and concentrate, where for several years past hardly that many were taken up in several days. The snow is beginning to go off more rapidly, and prospectors are eagerly waiting to begin the season's campaign. Shipments from Silverton in April totaled 142 carloads, an increase of 10 over March. At the Sunnyside mine wages have been raised from 25 to 50c. per shift, the highest being $4.50.

GEORGIA

In Lumpkin and adjoining counties are extensive deposits of feldspar, said to be sufficient to yield enough potash to fertilize all the crops this State can raise for several years. Plenty of water-power is available for grinding. Capital is necessary for exploitation.

MICHIGAN

THE COPPER COUNTRY

(Special Correspondence.)—Continued improvement is reported from the White Pine ore, the average in April being 27 lb. refined copper per ton. The tailing loss is 11 lb., but this is being reduced. Costs are under 10c. per lb.

At the White Pine Extension the shaft is to be sunk 250 ft. before opening out. Shale found in the shaft confirms drill-cores.

Houghton, May 5.

MISSOURI

JASPER COUNTY

A 400-ton mill is proposed for the Barrett land in the Porto Rico district by a new company, in which A. Gibson of Joplin is largely interested.

The ore market at Joplin was a trifle stronger last week, when average prices for blende, calamine, and lead were $97, $71, and $96 per ton respectively. The output of the Missouri-Kansas-Oklahoma region was 8051 tons blende, 763 tons calamine, and 1033 tons lead, with a total value of $942,400.

ST. FRANCOIS COUNTY

Wages in the lead region have been advanced 10%, making a total increase of 30% in 15 months. Over 7000 men benefit.

On May 9 about 2000 underground shovelers at the Federal and Doe Run mines downed tools, demanding $3.50 a shift and that only 20 mine-cars be filled in 8 hours.

MONTANA

FERGUS COUNTY

During April the Barnes-King company produced 3592 tons of $6.37 and 2933 tons of $4.09 ore, a total yield of $34,900.

GRANITE COUNTY

In the Dunkelberg district, Makeever Bros. of New York have been doing considerable diamond-drilling with interesting results at their Wasa, Hollander, and Dunkelberg properties.

LEWIS AND CLARK COUNTY

Rich copper-silver ore has been discovered in the Wolf Creek district, 35 miles north of Helena. The lode is in limestone near a diorite contact. A little south of this Hudson brothers and Bissoinette have opened similar ore.

At the Porphyry Dyke mine in the Rimini district the Anaconda company is employing between 40 and 50 men. W. A. Clark, Jr., and the Barnes-King company are interested in other properties.

SILVERBOW COUNTY

With W. L. Creden in charge the old Ophir mine, in the south-west part of Butte, is being re-opened. The mine and mill equipment only require a little overhauling. The shaft is 1065 ft. deep, and when unwatered will be sunk to 2500 ft.

On April 26 the Boston & Corbin mill started working two shifts, producing 6.7% concentrate. Some good ore is extracted from the 900-ft. level.

NEVADA

HUMBOLDT COUNTY

In the north drift at 1600 ft. in the Seven Troughs Coalition 30 in. of $1484 ore has been opened. Work on the south is also encouraging.

LINCOLN COUNTY

In April the Prince Consolidated at Pioche shipped 14,072 tons of ore. The 200-ton flotation plant for the tailing at Bullionville has been ordered.

White Pine County

(Special Correspondence.)—A shipment of crude ore, which contains 78% tungstic acid, has just been brought in from the camp of Big Wash, on the east side of the Snake range, by W. F. Chapman, connected with Atkins, Kroll & Co. This property is owned by Mr. Chapman and W. Taylor, and this shipment is one of a series of the highest grade ever made from crude ore without concentration. The ore is crystallized scheelite, and contains some rare and beautiful specimens, the crystals being translucent and having the general appearance of calcite crystals. Work has been in progress on the property throughout the winter, and a number of other shipments of the same grade have been made, all of them averaging over 78%. The ore occurs as irregular deposits in a belt of metamorphosed limestone 200 ft. wide, and operations might be classed as pocket-mining. From one of these pockets a single chunk of this high-grade ore was taken, weighing 320 lb. Among the specimens Mr. Chapman brought with him on this trip to Ely was a large geode, 8 to 10 in. diam., the interior of which is lined with pure crystals of scheelite. He considers that the east side of the Snake range will prove to be as important a producer of tungsten ores as the west side, on which are the camps of Tungstonia, Scheelite, Tungsten, and Minerva. On the east side the districts that are now gaining prominence include Big Wash, Beaver creek, Snake creek, Lexington, Baker, Fowler, and Garrison.

Ely, May 10.

The Nevada Consolidated Copper Co. reports as follows for the first quarter of 1916:

Ore treated, tons	827,880
Average content, per cent	1.66
Metal output, pounds	19,160,274
Average price received, cents per pound	23.478
Cost, cents per pound	9.65
Profits	$2,781,811
Dividends (2)	999,728
Net balance to surplus	$1,556,225

IDAHO

Shoshone County (Coeur d'Alene)

Owing to the high wages in the Coeur d'Alene the banks at Kellogg and Wardner have greater deposits than ever before. On account of the new smelter a land boom has hit Kellogg.

To improve the Y. M. C. A. play-grounds at Kellogg the Bunker Hill & Sullivan company has donated $1500.

The coming season promises to record unusual activity among the mines of the Mullan district, many of which have been dormant for several years.

The following figures are from statements made to the county assessor regarding results in 1915:

Company	Ore mined tons	Gross value	Cost of extraction	Freight and treatment	Improvements and repairs	Net profits
Bunker Hill & Sullivan	454,205	$4,177,819	$1,119,584	$1,793,275	$136,746	‡$1,145,855
Hecla	146,675	1,422,579	388,340	393,588	46,970	593,680

*Shipping product. †Includes freight, treatment, and betterments. ‡Includes $17,642 royalties.

NEW MEXICO

Grant County

The Chino Copper Co. reports as follows for the first quarter of 1916:

Overburden removed, cubic yards	746,209
Ore treated, tons	714,400
Average copper-content, per cent	1.8719
Recovery, per cent	60.82
Metal output, pounds	16,267,450
Price received, cents per pound	26.566
Cost, cents per pound	8.95
Profit	$2,746,987
Dividends paid ($1.25 per share)	1,087,475
Surplus remaining	1,659,512

The copper yield was less than in the preceding term.

TEXAS

El Paso County

At the El Paso smelter of the A. S. & R. Co. there are 328 cars of ore on the tracks awaiting discharge, therefore a temporary embargo has been placed on the quantity to be sent by ore producers. Two more converters are being installed, but delivery of parts is slow. There has been trouble in securing the proper magnesite brick for lining the converters.

UTAH

Iron County

Advice from Cedar City states that east of Parowan and Paragonia extensive deposits of high-grade potash have been discovered, occurring like those in Germany.

Juab County

Tintic mines shipped a total of 222 cars of ore during the week ended May 13, the largest for many years. The principal producers were the Chief Consolidated, Dragon, Iron Blossom, Centennial Eureka, Mammoth, Eagle & Blue Bell, and Gemini. All employees in the district have received another raise of 25c. per shift. Miners now get $4 per day.

Salt Lake County

The Alta Tunnel & Transportation Co.'s adit in the Big Cottonwood is in over 2000 ft., in black limestone formation. A heavy flow of water is reported. The adit is to be 4000 ft. long to connect the two Cottonwoods. The general manager, F. V. Bodfish, said the following about this project:

"The Little Cottonwood district has heretofore been a high-grade area, that is, nothing but this class of ore could be shipped at a profit. This has been due to the cost of transportation. There are enormous tonnages of $10 ore in the dis-

trict. The Alta tunnel will open those properties at from 800 to 1100 ft. from the surface. The ore can then be dropped into the cars, and a transportation company has been organized to haul it to Murray. I am informed that caterpillar-tractors will be used, and the engineers assure me that the ore can be laid down at Murray at a cost far below the present charge of taking the ore from the district by way of the Little Cottonwood district. The tunnel will also afford better drainage facilities for the various properties, as it will cut during its course all of the principal fissures that traverse the district."

Ten inches of high-grade lead-silver ore has been cut in a raise 28 ft. above the adit, and 800 ft. from the portal.

The Cardiff company is paying 25c. per share on June 1. In the mine the rich shoot has been opened for 200 ft. Three shifts are employed. Small shipments are made at present.

At the Baker mine, near the Maxfield, the adit is in over 800 ft., and recently cut two promising fissures.

The suit of H. J. Wheeler and other land-owners in the vicinity of Tooele v. the A. S. & R. Co., for alleged damage to their properties by smelter-fume, is being heard at Salt Lake City.

The Utah Copper Co. reports as follows for the first quarter of 1916:

Overburden removed, cubic yards	1,379,295
Ore treated, tons	1,984,600
Average content, per cent	1.4333
Recovery, per cent	64.27
Metal output, pounds	36,564,533
Price received, cents per pound	26.131
Cost, cents per pound	7.19
Profit	$6,186,414
Dividends paid	4,061,225
Surplus, including other income	$2,018,605

Winter affected the metal output considerably.

Summit County

The output of the Park City district in April was 6910 tons of ore and concentrate. The Silver King Coalition contributed 2714 tons; Silver King Consolidated, 107 tons; Judge Mining & Smelting Co. (late Daly-Judge), 2252 tons; and Ontario, 483 tons.

MEXICO

The mining outlook in Mexico, according to F. M. Estes, with the A. S. & R. Co. at Spokane, Washington, and who was five years in Mexico, especially in the northern part, is dismal. After five years of continuous revolutions, Americans long resident there have given up even guessing about the outcome. When he left Sonora intervention seemed inevitable, but it now looks as if there might be co-operation with the Constitutionalist government. The Americans in Mexico would have preferred intervention at the start of the trouble, and they feel that the situation brought about by the border bandits should have been cleaned up four years ago.

Hidalgo

The profit in treating 25,904 tons of ore at Santa Gertrudis in March was $106,000.

Jalisco

(Special Correspondence.)—The mining companies shipping bullion from the port of Manzanillo on the west coast, to San Francisco, California, have been notified by telegraph by the Agente Aduanal of Manzanillo, that no bullion can be exported without special permission from the Secretary of Hacienda. This advice was received April 29, and so far no reply has been received to telegrams asking for that special permission. English speaking people in Guadalajara are united in their praise of the article on Mexico that appears on the first page of *The Saturday Evening Post* of April 29. Every bit of it is correct and to the point.

Guadalajara, May 1.

PERSONAL

Note. The Editor invites members of the profession to send him particulars of their work and appointments. This information is of unquestioned interest to our readers.

H. J. Shearer has gone to Siskiyou county.

H. P. Gordon is now at Atolia, California.

Fowler Rickard is again at Lovelock, Nevada.

Corey C. Brayton has gone to Salt Lake City and Butte.

Maurice D. Leehey, of Seattle, was here during the week.

P. D. Burt is at the Old York mine near Congress, Arizona.

A. W. Newberry sails from New York for South America on May 27.

George Randolph is manager of the Adanac silver mine at Cobalt.

S. F. Shaw is visiting mines in the districts adjacent to Salt Lake City.

Willard Mallery has returned from British Columbia to San Francisco.

George O. Bradley, of Bradley, Bruff & Labarthe, was at Miami last week.

A. E. Drucker sailed for London from New York on the *Noordam* on May 11.

Frank Oldfield has returned to Los Angeles from Cinco Minas, Jalisco, Mexico.

Frank M. Estes, late of Sonora, Mexico, is resident engineer for the A. S. & R. Co. at Spokane.

John E. S. Clark, of Riverside, California, was married recently to Miss Ellen J. V. Preterre.

E. W. Mills and J. F. Manning will be arriving in San Francisco from Korea late in August.

Burt E. Cartwright, formerly president of the Temiskaming Mining Co., is president of the Adanac Silver Mines, Limited.

Guy C. Riddell, until recently at the East Helena smelter, has received an appointment with the Associated Smelters in Australia.

T. R. Hunt has resigned the management of the Syndicate Mining Co., Aroroy, P. I., to be succeeded by Joseph J. Shaw. Mr. Hunt's present address is 2941 Denver Place, Denver.

James T. Kemp, son of Professor Kemp of Columbia, is one of the three graduates from the Columbia School of Mines to receive the Illig medal for exceptional proficiency; the other two are John P. Hubbell and Joseph Kuchar.

Obituary

John Winthrop Chandler, superintendent of the West End and other mining properties at Tonopah, died on May 7 in San Francisco.

Frank G. Janney, well known through his connection with the Utah Copper Co., advisory metallurgist to the group of copper and zinc companies controlled by D. C. Jackling, and one of the leading specialists in flotation, died at Los Angeles on May 12, after an operation for appendicitis, at the age of 50 years. He leaves a wife and family, two sons being already honorably prominent in Western metallurgy.

The Chemists' Club of New York announces the establishment of a scholarship fund, the income from which, approximately $500 a year, is to be devoted to assisting financially deserving young men to obtain education in the field of industrial chemistry or chemical engineering. This scholarship has been endowed by Victor G. Bloede, a prominent manufacturing chemist of Baltimore. Its benefits will be open to properly qualified applicants without restriction as to residence, and may be effective at any institution in the United States, which may be designated or approved by the Club.

THE METAL MARKET

METAL PRICES

San Francisco, May 16.

Antimony, cents per pound	39.50
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	7.75—8.75
Platinum: soft metal, per ounce	$80
Platinum: hard metal, 10% iridium, per ounce	$84
Quicksilver: per flask of 75 lb	$90
Spelter, cents per pound	22
Tin, cents per pound	50
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, May 16.

Antimony: 50% product per unit (1% or 20 lb.)	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	12.50
Manganese: 50% metal, 8% silica, per ton	12.00
Tungsten: 60% WO_3, per unit	50.00

At Boulder, Colorado, tungsten producers expect the price to remain steady at $60.

EASTERN METAL MARKET

(By wire from New York.)

May 16.—Copper futures continue strong; lead is stronger but uncertain; spelter is dull and weak.

COPPER

Prices of electrolytic in New York, in cents per pound.

Profit taking probably caused the recent set-back in silver. If the large stocks of metal held by producers are judiciously sold the market should not be flooded, and so affect prices. Heavy buying for Russia is a recent stimulating factor.

The absence of sales from Mexico, the paucity of supplies from the United States, the ready absorption by the Indian Bazaars of sales of silver direct from China, and the almost complete realization of China holdings in London, accounts for the difficulty of feeding the present demand, even though buyers act with discretion, recognizing that pressure must inevitably force up the price, according to Samuel Montagu & Co. of London. The demand of Indian Bazaars has been met direct from China, and they have therefore not figured much as buyers in the London market. The bulk of enquiry recently has been for coinage for the British Empire and elsewhere, as it has been during preceding weeks. The reserve of silver coin in India fell 139 lacs (over 5,000,000 oz.) between the 7th and the 15th of April. Apparently this does not take into account certain purchases, believed to be on account of the Indian government. It was rumored in the Indian Bazaars that the two large shipments of silver from China to India (6,000,000 oz.) were to be coined into Egyptian 'piastres' at the mints of the Indian Government. The 'Temps' states that the French mint, which in ordinary times coined annually 8,000,000 to 10,000,000 francs in silver, will, this year, coin more than 80,000,000 francs, and that purchases of silver are probable to an extent of 400,000 kg. (12,800,000 oz.) at a cost of more than 40,000,000 francs. The issue of silver coin in England in 1914, £6,092,569, greatly exceeded the issue of any previous year, and was more than 6½ times the average of the previous 10 years. Stocks in London at the end of April were only worth £500,000, say 3,750,000 ounces.

LEAD

Lead is quoted in cents per pound, New York delivery.

Eastern Metal Market

New York, May 10.

Dullness characterizes the entire non-ferrous metal market. So uninteresting has it become that it is almost dead in all departments, except perhaps in copper. This metal is stronger and firmer than the others and prices have been maintained unchanged. Probably the general stagnation is due as much as anything to uncertainty in European and Mexican affairs. Stocks of most metals in the hands of consumers are probably plentiful, with scattered exceptions. In all metals but lead and copper, weakness has developed to an extent sufficient to depress prices. In no market do any features of significance stand out. A brief summary would be about as follows: Copper is dull but firm; lead, very dull and unchanged; tin, quiet and lower; zinc, inactive with lower prices; antimony, plentiful and cheaper, and aluminum stationary.

The strike situation, which was menacing even to the steel trade last week, is now much better, especially in the Pittsburg district. The feature of the week in the steel circles has been the reported placing of about 150,000 tons of shell-steel in the shape of blooms and rounds. Negotiations for as much more, with 50,000 tons for Russia and Italy, are also conspicuous. As high as $80 to $85 per ton is reported paid for blooms, and 3.50 to 3.75c. per lb. for rounds.

COPPER

Rumors of large orders from foreign sources about to be placed have again come to the surface, but so far are not confirmed. In some quarters they are regarded as only talk or efforts to cause activity. Prices have remained stationary and electrolytic copper for May delivery can be secured at 30.50c., though this quotation is nominal. For far future it is quoted at 28.75c. from September on. Lake copper for the same future delivery is about 29 to 29.50c. In general, however, dullness prevails, though the underlying tone is strong. Contradictory reports prevail, rendering a clear view of the actual conditions difficult, because some sellers claim that there is a good demand for prompt metal, while others affirm the opposite. It is reported, however, that such offers in some quarters have been unavailing. The only business actually done has been a fair movement in arsenical Lake copper. The fact that brass rods and disks are easier, and that the inquiries for rods are fewer, might indicate a slackening in the demand for munitions. The rather extended advance in the London market for electrolytic copper from £145 a week ago to £153 10s. yesterday shows emphatically how futile have been the efforts of the Government to keep the price at £100 or less.

ZINC

Dullness and weakness are prevailing factors, and as a consequence quotations have declined to 17c., New York, for prompt delivery, and to 16.75c., St. Louis. June zinc can probably be obtained at about 16.25 to 16.50c., with July at about 15.75c. and last quarter at around 13.25c., all St. Louis. There has been a slight revival in demand in the last day or two and the tendency is toward a firmer tone. There seems to be a noticeable lack of demand from the brass interests, which is more noteworthy because they are understood to have contracted for copper for the remainder of the year. Galvanizers come into the market only now and then, but they buy but little or only what is absolutely necessary. Sheet zinc is quoted at 25.50c., base. Exports to May 10 were 1937 tons.

LEAD

The decline, strongly in evidence recently, has been checked, but the market is lifeless though fairly steady. The quotations of both the A. S. & R. Co., and the independents are the same, 7.50c., New York, and 7.37½c., St. Louis. In the St. Louis market a tendency to weakness has been suspected, but nothing has developed beyond the sale of 100 tons at 7.32½c. last week. As low a bid as 7.25c. is not considered safe unless the buyer is ready to make good. Some consumers are evidently reduced to a minimum as to stocks, while others are well supplied and ready to dispose of some. Any buying of consequence would immediately strengthen the situation. Sellers in general are restive, but unwilling to enter any competitive price reduction. Lead exports to date were 397 tons.

TIN

The week has been devoid of interest or much activity. Except on Friday of last week dullness has controlled the market. On that day there appeared a strong demand for futures, and 200 to 300 tons was reported sold. Consumers are supposed to be fairly well covered in their supplies, and are consequently disinclined to make any purchases. Spot tin was 49.75c., New York, yesterday, a decline from 51.50c. a week ago. Lack of demand is the controlling feature, with arrivals at 1020 tons to date and 4000 tons reported afloat.

ANTIMONY

A distinct weakness has appeared because of large arrivals and a decided falling-off in demand. Chinese and Japanese grades, spot deliveries, can now be obtained for 35c., duty paid.

ALUMINUM

Heavy buying by Russia is reported, but prices are unchanged at 58 to 60c. for virgin aluminum, No. 1.

ORES

Antimony: The ore is easier, with prompt business done at $2.50 per unit, and forward sales at $2.50.

Tungsten: The present situation is rather extraordinary. About a month ago price was a minor consideration. Lately, however, arrivals from South America, together with a combined effort by buyers, have depressed the market and the purchasers will not make a price, every offer being met with the reply, "No interest." No business except in small lots is reported the past week. The nominal quotation therefore is $60 for spot and $50 for forward concentrates, with no sellers at the figures.

Copper Refining in the United States

The 10 copper refineries of the United States will have a combined annual capacity of 2,461,000,000 lb. upon the completion, within a few months, of additional equipment.

The capacities will be as follows, in pounds, according to the *Boston News Bureau:*

Refinery	Monthly		Annual
A. S. & R. Co.			
Baltimore	40,000,000		
Perth Amboy	28,000,000	84,000,000	1,008,000,000
Tacoma	16,000,000		
Anaconda:			
Raritan	40,000,000		
Great Falls (new)	15,000,000	60,000,000	720,000,000
Great Falls (old)	5,000,000		
Nichols Copper Co		35,000,000	420,000,000
United States Smelting		17,000,000	200,000,000
Balbach		4,000,000	48,000,000
Calumet & Hecla		5,400,000	65,000,000
Total		205,400,000	2,461,000,000

COMPANY REPORTS

ANACONDA COPPER MINING CO.

During 1915 the capital of this great company was altered from 6,000,000 shares of $25 each to 3,000,000 of $50. For the sum of $6,624,583 all the capital stock of the United Metals Selling Co. of Delaware was acquired. There was also bought from the Amalgamated Copper Co. 150,000 Inspiration and 30,800 Greene-Cananea shares, etc., costing $4,769,900.

At the beginning of the past year operations at Butte, Montana, were on a reduced basis, but a great deal of overhauling was done in the meantime. By May work was at normal, and at the end of 1915 on a larger scale than ever.

Development in the mines totaled 35.31 miles, against 33.15 miles in 1914. Shaft-sinking aggregated 4980 ft. Results generally at depth were highly satisfactory. There was extracted 4,376,557 tons of ore, and 6783 tons of copper precipitate from mine-water.

The Washoe works at Anaconda treated 4,421,629 tons, and those at Great Falls 384,066 tons. Of this, 535,223 tons was from other companies. Metal production in the past three years was as follows:

Metal	1915	1914	1913
Copper, pounds	254,311,574	223,720,292	270,301,644
Gold, ounces	106,703	99,651	64,898
Silver, ounces	9,005,618	8,314,116	10,321,296

On the 1915 total, the Anaconda mines yielded 235,076,289 lb. copper, 106,703 oz. gold, and 8,064,986 oz. silver.

The coal mines in Montana and Wyoming produced a total of 678,731 tons, a good deal of which was sold. The lumber departments cut 86,645,962 ft. of timber, and purchased 29,110,829 ft. The balance on hand on January 1, 1916, was 94,495,273 ft. Other subsidiary departments did a good business, all showing a profit of $687,454. The company did extensive exploration at the Potrerillos mines in Chile, and acquired further property at Butte and near Helena.

Financial results were as under:

	1915	1914	1913
Sales of metals	$61,473,677	$36,745,559	$44,003,473
Gross revenue, with metals on hand	87,273,886	51,533,659	61,258,755
Disbursements	67,806,191	42,335,241	49,995,529
Balance	$19,467,695	$9,198,419	$11,283,226
Income from investments	112,922	.....	.....
Interest	984,233	408,831	40,271
Depreciation	1,900,578	.....	.....
Profit	$16,695,806	$8,789,587	$11,323,497
Dividends	9,325,000	9,077,500	12,997,500
Surplus	7,370,806	*287,913	*1,674,003
Profit and loss surplus	$15,051,865	$7,681,059	$7,021,170

*Deficit.

Subsidiary corporations:

International Smelting Co.

The plant at Tooele, Utah, treated 270,374 tons of copper ore, and 395,574 tons of lead ore, yielding 14,271,174 lb. copper, 113,002,657 lb. lead, 48,020 oz. gold, and 5,090,157 oz. silver. The plant at Miami, Arizona, reduced 70,304 tons of concentrates and 17,105 tons of ore, producing 51,769,669 lb. copper, 822 oz. gold, and 70,000 oz. silver. The works only commenced on May 21, 1915.

International Lead Refining Co.

This company treats lead bullion from Tooele at East Chicago. There was refined 55,376 tons of lead and 2266 tons of foreign ore, yielding 103,121,355 lb. of common and corroding lead, 9,164,073 lb. antimonial lead, 18,136 oz. gold, and 4,031,610 oz. silver.

Raritan Copper Works

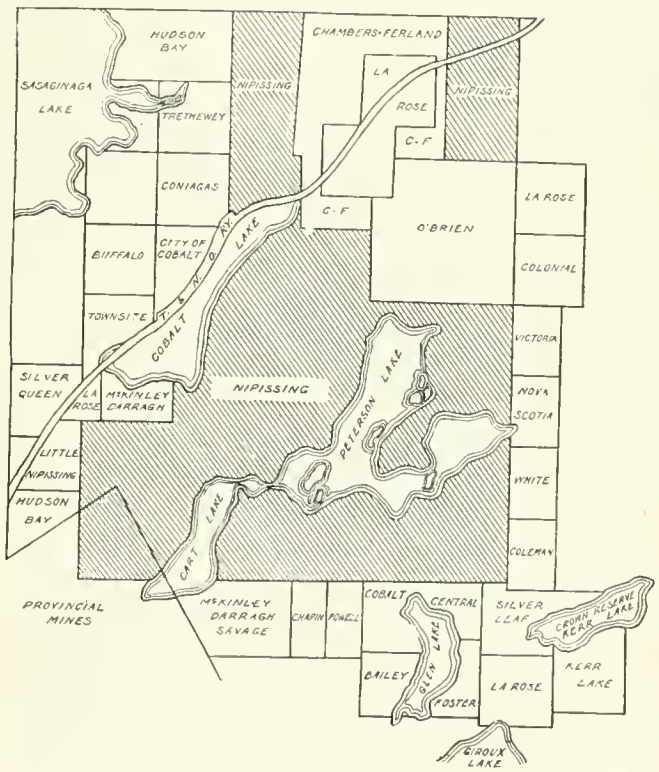
This company's refinery is at Perth Amboy, New Jersey, and treated for all companies 162,282 tons of copper bullion and 719,343 oz. of silver, giving 323,850,718 lb. copper, 174,408 oz. gold, and 16,025,993 oz. silver.

Butte, Anaconda & Pacific Railway Co.

This company's electric roads transported 6,506,525 tons of ore and freight and 230,684 passengers, for a gross revenue of $1,627,476. The profit was $480,029. The dividend of 6% amounted to $150,000.

NIPISSING MINES CO.

The 1915 report of this great silver producer is of interest. The general manager, R. B. Watson, states that the period was one of uncertainty, both as to the price of silver and the cost of supplies; therefore production was not pushed beyond the tonnage necessary for dividends. The average price received in London for 4,097,391 oz. was 50.06c. per ounce. The cost of production was 19.06c. per ounce, a decrease of 0.74c. The mine has never shown ore reserves commensurate with its annual output, but its history during 12 years shows that development of new ore has kept pace with current production. Reserves are estimated as 2512 tons, assaying 1814 oz. per ton, and 180,236 tons of 24.2 oz. ore, making total contents 8,921,718 oz. Exploration of the Cobalt Lake fault revealed several rich shoots, the last one below 450 ft. A shaft, No. 81, is now being sunk to further prove the fault.



COBALT MINING DISTRICT, SHOWING PROPERTIES OF NIPISSING MINING CO., LTD.

Surface prospecting by hydraulicking did not disclose any veins of importance. Underground development totaled 10,496 ft., and 503 ft. of diamond-drilling.

The high-grade mill treated 921 tons of 2474-oz. ore from the Nipissing, and 553 tons of 2917-oz. ore from other mines. The low-grade plant treated 77,183 tons of 31.49-oz. ore with 87.52% recovery. Forty stamps averaged 6.57 tons per day each. The mill was closed three months through lack of power. The refinery produced 6,164,239 oz. silver. Cost of treating low-grade ore was $3.913 per ton.

Total costs were reduced from $11.60 to $10.02 per ton of ore. The net revenue was $1,441,128. Dividends amounted to $1,200,000. The surplus is $1,786,261, an increase of $183,000. The output to date is 11,209,238 oz. silver.

TENNESSEE COPPER CO.

On ore yielding 26.83 lb. of copper per ton the operating cost of production at this property was reduced to 8.76c. per pound. The average price received for the year was 16.274c. per lb. on an output of 12,750,418 lb. of copper. Early in the year the War affected the manufacture of sulphuric acid, but after improvements were made to the plant, it was operated at full capacity. The output of acid was 210,666 tons, a slight increase over that of 1914. A large addition is being made to the plant. These notes are from the report of the president, Utley Wedge.

The manager, J. B. Risque, states that at the Burra Burra mine underhand stoping has been discontinued, the output of ore coming from back stopes. Electric haulage is in use on No. 3 and 6 levels with satisfaction. Broken ore in stopes amounts to 250,000 tons, double that of a year ago. Diamond-drilling from No. 8 level showed continuity of the orebody in size and value for 400 ft. New machinery at the McPherson shaft is about complete. Some work is being done at the London and Polk County mines. M. A. Caine, superintendent of mines, reported that development totaled 1904 ft., and drilling 1042 ft. Ore reserves are estimated at 3,707,121 tons, a decrease of 303,240 tons. This is on account of the small amount of development, but does not include the reserve disclosed by the drill. There was extracted 511,940 tons of ore, at a cost of 93.633c. per ton.

The smelter reduced 635,630 tons of mixed material, using 28,472 tons of coke. Two Great Falls type basic converters are to replace the small ones now in use. The total cost per ton of ore in all departments was $2.352.

The revenue from acid, copper, gold, and silver was $3,862,159, of which $1,298,037 was profit. Dividends absorbed $600,000. The surplus at the end of the year was $458,158, compared with $50,767 at the beginning.

CONSOLIDATED ARIZONA SMELTING CO.

In his report for the past year, the general manager, G. M. Colvocoresses, covers operation of the smelter at Humboldt and the Blue Bell and De Soto mines:

In the Blue Bell development amounted to 2743 ft., opening 165,000 tons of new ore. The shaft was sunk 150 ft. to 1000 ft. depth. Reserves are estimated at 235,000 tons, averaging 3.5% copper and $1.50 gold and silver. Prospects for a large increase in tonnage are good. A new hoist of 2000 ft. capacity was erected. The output was 82,171 tons, assaying 2.97% copper and $1.40 in precious metals. This was an increase of 26,171 tons over that of 1914. The current year will also be greater. All mining charges were $2.629 per ton. The De Soto mine was re-opened and fully equipped, producing 8360 tons of ore, containing 3.5% copper and $1.50 gold and silver. The present output is at the rate of 40,000 tons per year. Reserves are 65,000 tons. Eight ore-shoots, none very large, are being mined. The future of this mine is also good.

The mill treated 81,544 tons of ore and tailing, averaging 2.83% copper, with 88.6% recovery of this metal, 62.5% of the gold, and 70.5% of the silver. There was produced 19,877 tons of 10.27% copper concentrate. Results were far in advance of those for 1914. The cost, including flotation royalty, was $1.20 per ton, against $1.82 in 1914, and $2.09 in 1913. Only gravity concentration was employed in the latter year. The plant's capacity is to be increased from 240 to 500 tons daily.

The smelter reduced 61,034 tons material, yielding 5,762,974 lb. copper, 3092 oz. gold, and 81,647 oz. silver. Of the copper, 1,370,974 lb. was custom metal. The cost of reducing to matte was $3.34 per ton, a reduction of $2.21 per ton, and the cost of converting matte to blister copper was $0.0046 per pound of copper. A new 19 by 100-ft. reverberatory was built, now working with the 19 by 60-ft. furnace. The enlarged smelter enables custom work to be profitably done. The total cost of producing copper was 13.327c. per pound, against 13.92c.

New construction amounted to $155,272, at the mines and plants. The manager recommends that $15,000 be spent each month on similar work as deemed expedient, eventually reducing the cost of production. The year's profit was $194,943.

EAST BUTTE COPPER MINING CO.

A comparison of the last three years of this Montana company shows the following results:

	1915	1914	1913
Ore mined, tons	150,911	72,853	105,071
Copper content, per cent.	4.28	4.72	5.16
Ore smelted (inc. custom), tons	181,063	110,992	186,815
Copper produced, pounds	12,542,058	9,175,579	14,401,108
Gold produced, ounces	2,696	2,219	8,803
Silver produced, ounces	318,124	242,347	506,897
Gross income	$ 2,753,588	$1,455,454	$2,645,568
Cost, cents per pound	11.85	11.11	11.04
Price received, cents per pound	19.31	13.57	15.08
Profit	$ 782,988	$222,253	$531,772

Development in the Pittsmont mine amounted to 6226 ft., over ½ on the 1500-ft. level. The main shaft was sunk from 1770 to 1828 ft., a heavy clay gouge at this depth stopping sinking. As the water is drained from the fault-plane, resumption of sinking can be proceeded with. Work on the upper levels opened a good deal of new ore.

An 800-ton flotation plant was erected to treat tailing and slime from the concentrator and old dumps. Re-modeling of the blast-furnaces was completed early in 1915. These two improvements cost $136,000. In March, 1916, the plant produced 1,300,000 lb. of copper.

UTAH CONSOLIDATED MINING CO.

According to the manager, Fred. Cowans, ore reserves of this Utah company are 266,700 tons assaying 1.9% copper, 0.05 oz. gold, and 0.69 oz. silver; also 43,500 tons containing 16.21% lead, 0.7% copper, 0.04 oz. gold, and 4.96 oz. silver. There is also over 100,000 tons of low-grade ore, profitable with high metal prices. Development and exploration totaled 19,890 feet.

There was shipped to the International smelter 207,119 tons of copper, and 65,129 tons of lead ore, yielding 8,836,091 lb. copper, 17,777,604 lb. lead, 370,985 oz. silver, and 19,387 oz. gold. Smelting cost $705,957.

Revenue from metals was $2,298,657. The profit was $1,128,122. Dividends amounted to $600,000. Copper bullion on hand is valued at $1,075,304.

RIO TINTO COPPER CO.

The past three years of this company operating in Spain show the following results:

	1915	1914	1913
Copper production, tons	not published	21,515	36,320
Average price received per ton	£72 12s.6d.	£59 9s.4d.	£68 5s.9d.
Profit	£1,129,821	£737,379	£1,557,877
Preferred dividends	81,250	81,250	81,250
Common dividends	1,031,250	656,250	1,406,250
Surplus	159,267	162,439	185,872

The reports are each year giving less data, that for 1915 being the first to omit the quantity of metal produced. In 1912 the profit was £2,090,702.

In the first quarter of 1916 the Nevada Hills profit was $16,424 from 12,366 tons treated.

EDITORIAL

T. A. RICKARD, Editor

FROM a copy of the decree issued by the Mexican government, we note that the tax on the exportation of ores is at the rate 10% *ad valorem* on the silver as well as the gold contained therein. On other metals the rate is 5%. On claims from 1 to 10 pertenencias an annual tax of ₱6 Mexican or $3 American is levied, the rate rising to ₱24 Mexican or $12 American on gold and silver mining property covering over 100 pertenencias. However, these taxes are likely to be modified in consequence of protest from Washington. Taxation without government is not in accord with democratic ideas.

DISAPPOINTING results from the big consolidations on the Rand, notably the East Rand Proprietary, Randfontein Central, and Crown Mines, have put a quietus on the old notion that the banket continued uniformly rich to an indefinite depth. In a recent issue *The Financial Times*, in London, says: "The truth is that the hard logic of events is compelling those in control of most of the leading Rand properties to a tardy, if tacit, admission of the theory to which we were among the first to give publicity years ago, that the value of the reefs in this wonderfully productive goldfield is slowly but surely deteriorating in depth." Many years ago the present writer mentioned the fact, not the theory, that even Methuselah died.

UNDER 'Discussion' we publish a letter from Mr. W. J. Sharwood, metallurgist at the Homestake, on the occurrence of nitrogen gas in metal mines. Mr. John M. Nicol, who wrote the articles on the saving of fine gold published by us last year, discourses on patents, and argues that the present system is so cumbersome as to cause many valuable ideas to remain buried. He insists that the originator of a basic idea is rewarded too little, while those who develop and copy it are enriched disproportionately. Our Mr. P. B. McDonald comments on a recent editorial on the way to success in mining engineering and himself advises deliberateness of purpose. A letter from Mr. J. D. Hubbard, who is engaged in drift-mining, contains a number of useful data concerning the cost of this kind of alluvial operation.

COURSES in foreign trade are announced. The Bureau of Foreign and Domestic Commerce, in the United States Department of Commerce, has organized an educational course in foreign trade with a view to training men for intelligent participation in the expansion of business believed to be assured in the near future. Dr. Edward E. Pratt, chief of the bureau mentioned, is directing the instruction, and he is assisted by Messrs. O. P. Austin, E. N. Vose, E. A. De Lima, Emory R. Johnson, and G. G. Huebner, all of whom are specially qualified for the work. The course covers a treatment of the various factors entering into export trade and is supplied to corporations or firms at a moderate cost, for study by their employees.

NEVADA has a local section of the American Institute of Mining Engineers, as is recorded in detail on another page. This new departure, organized at Reno on May 18, was signalized by the presence of Mr. W. L. Saunders, ex-president of the Institute, who delivered one of his characteristically happy speeches. A propitious start was made, the co-operation of the Governor of the State being conspicuous, as well as that of the local School of Mines, led by two professors, Messrs. F. C. Lincoln and J. C. Jones. The profession was further represented by such distinguished practitioners as Messrs. Charles Butters and Whitman Symmes. It was high time that our friends on the other side of the range had their own local organization and rallying point. We wish the Nevada section every success.

SPEAKING of patents, we note that the British government is taxing royalties on patents at the unearned income-tax rate, whereupon a controversy has arisen with the Chancellor of the Exchequer. It is claimed that "the case of the inventor is different from that of the author, for invention can hardly be regarded as a profession. It is usually accidental in its manifestation, and when it leads to patent rights with a marketable value the sale of them has little of the character of annual income." To this most of us in this country will demur. An inventor's occupation is likely to be quite as regular as an author's. Consider Mr. Edison. As to the regularity of returns, simulating an income, ask Minerals Separation Ltd.; or if they are secretive, ask their licensees. No, the British view of the subject is not commendable.

FALLACIES die hard. One of the most pernicious is the notion that fire-assays fail to discover the real value of many ores of gold or silver. Of course, if the assayer is an ignoramus, he will miss his object, and in some rare complex ores the ordinary methods may break down, but to assert that there is more gold and silver in most ores than the average assayer can detect is not true. The statement is used to deceive the ignorant and to promote bogus schemes of treatment. We have before

us a booklet now being circulated in Alaska in which a company claims to extract $20 to $90 in gold from ores that yielded from $2.10 to $16 by the "old fire assay." It is explained in this prospectus that "the same flux was used and all charges carefully weighed. The heat of the furnace was kept as nearly uniform as possible." From our own personal experience of assaying we are able to state that this is rot. We warn our readers against the imposition.

CHLORINE is one of the most valuable of chemical agents. It has played an important part in the metallurgy of gold and silver, but efforts to extend the use of it to the extraction of the base metals have met with incomplete success as yet. Of the various methods, the most promising is the one identified with the name of Mr. John L. Malm, and, it may be added, Mr. S. A. Ionides, for these two metallurgists have collaborated in the development of the process. In this issue we publish a detailed and authoritative article on the theory and practice of dry chlorination as applied to ores of the base metals, written by Mr. Ionides. This article will serve as a timely corrective for an anonymous description of the process appearing in a recent issue of our New York contemporary. Whatever the immediate future of this phase of chlorination, it is obvious that the publication of details concerning the actual working of the Malm process and an explanation of its chemical rationale should clear the ground for further advance in this department of metallurgy.

WAIVER, by mutual consent, of apex rights between contiguous mining properties is a sensible way of preventing litigation. The four principal companies operating in the Miami district waived their extra-lateral rights in order to avoid trouble. It is now announced that the Detroit Copper Company and the Lazinskys have made a similar arrangement in the Morenci district. An earlier instance, which proved an example worthy of imitation, was the agreement between the Copper Queen and the Calumet & Arizona companies, in the Warren district. Mr. James Douglas, speaking for the Copper Queen, says of the agreement: "In spite of our close contiguity, and the many causes for friction that would inevitably have paralyzed the whole district under the working of the apex law, we have not only maintained friendly relations, but the terms upon which we agreed, when deciding to make our side and end lines carried down vertically the dividing limits of our properties, have immensely helped in the development of the Warren district, for when one company has made a discovery, the inspection of this discovery has been open to the officers of its friendly neighbor." This needs no further comment.

SILVER has been subject to further fluctuations, recorded elsewhere. The Mexican dollar, as *The Economist* says, "is now worth more dead than alive." Legally it is worth half the Mexican 50-cent gold dollar, namely 24½ cents, on May 3 it was worth 27 cents as unrefined bullion. If silver were to rise to 30 cents it would pay to ship rupees from India to London, and a lot of silver plate might go to the melting pot. However, in India a shortage of silver has been developed and the recent prosperity of the country is likely to cause a further strain on the available currency. In China, it is true, the Ministry of Finance is talking of a gold standard, but the political conditions render governmental action most unlikely. The *Temps* states that the French government will coin 80,000,000 francs in silver this year as against a normal coinage of 8,000,000 to 10,000,000 francs. Apart from minor causes, or even the decrease in production due to Mexican misrule, it is clear that the huge structure of credit now being created in Europe must have an ampler metallic base than is afforded by the output of gold.

LAST October we made mention of the American Association of Engineers, which was started at Chicago on September 14, and in our issue of October 16 we published part of a stirring address delivered by Mr. F. H. Newell. Since then the organization has been perfected and at the end of March a membership of 512 had been recorded, as we are informed by *The Monad*, a monthly publication issued by the new society. One of the first undertakings of the Association is to assist its members in obtaining employment by means of a service clearing-house. Another function is to give advice on patent and legal matters. The main purpose, as appears in the constitution, is "to raise the standard of ethics" and "to promote the economic and social welfare" of the engineering profession. Evidently there is an idea of awakening the profession to a sort of class consciousness and of winning the recognition of the community at large to the work done by engineers as members of the social organism. We are not without sympathy for this propaganda and look forward with interest to the growth of the Association.

WHAT is the richest stope you ever saw? This was the question put to a group of mining engineers in San Francisco a few days ago. A veteran instanced the face of ore at the boundary between the California and Virginia claims on the Comstock in 1876 at a depth of 1500 feet, where there was a width of 112 feet of $100 silver-gold ore. Another quoted the Lake View Consols, at Kalgoorlie, in 1890 when the end of the 300-ft. level showed 10 to 12 feet of 50-oz. gold ore, worth therefore about $1000 per ton. A third remembered the south end of the third level of the Broken Hill Proprietary in 1891 when 204 feet of ore averaged 50 ounces silver and 35% lead. Again there was the fifth level on the west vein in the Esperanza at El Oro in 1905 when a 4-ft. stope averaged $500 per ton. An engineer from Nevada mentioned the Hampton stope on the 235-ft. level of the Contention mine in 1909; this was 25 feet wide and averaged $200 per ton in gold. As to copper, the best any of us could recall was the 150-ft. level in the United Verde in

1884 when 85 feet of 35% ore was exposed. Thus the stope-faces mentioned had an assay-value in dollar-feet of 11,200; 11,000; 13,800; 2000; 5000; and 7600. Can our readers recall anything richer than these, omitting pocket-mining, of course?

FLOTATION was neglected at the last summer meeting of the American Institute of Mining Engineers, but full amends for such neglect is to be made at the meeting next September in Arizona. Among other methods of eliciting useful information on the subject., Mr. Dorsey A. Lyon, of the Bureau of Mines, at Salt Lake City, has issued a circular containing a questionnaire on flotation. We note that the queries include reference to the doubtful necessity for using agitation in all froth flotation, the question whether oil is a requisite, and the effect of an excess of it upon the operation. Another fundamental enquiry is that which asks whether the bubbles or the mineral particles are coated with oil, or whether the sole function of the oil is to modify the properties of the water. The electric theory is made the subject of a searching question and 'colloids' receive proper attention. An effort made in January, at a flotation conference in Kansas, to start a discussion on these same questions did not succeed as well as had been hoped, it being acknowledged frankly that much experimental work would have to be done before the basic uncertainties of the process could be removed. However, in any scientific investigation half the battle is to state the problem. We do not doubt but that the circulation of this questionnaire will stimulate thought and research to useful result.

WE have received a copy of the "agreement in regard to industrial conditions in the Clifton-Morenci-Metcalf district," the result of a conference between the managers of the Arizona Copper, Detroit Copper Mining, and Shannon Copper companies and a committee of 17 men, representing their employees in that district. Of the 17 men, 10 have Mexican names. The most important clause is the one providing that "all operations shall be conducted upon the open-shop principle." No discrimination shall be shown against union men, "the Western Federation of Miners always excepted." This covers the chief cause of the strike, which was started mainly because the management refused to deal with that anti-social organization. We note with pleasure that employees henceforth will not be obliged to trade at the company stores and that the intermediation of grievance committees elected by the men is authorized. Provision is made for the discharge of any foreman or shift-boss receiving 'tips' from his men as a factor favoring the holding of a job. The minimum wage for common Mexican labor is put at $2 per shift when copper is at 13 cents or over. Increases of wages are granted ranging from 5 to 15% over the wages paid previous to the conference, on a sliding-scale based upon the price of copper, from 13 to 17 cents, although it is a curious fact that copper was selling at 27 cents at the time when this agreement was made. To the mechanical crafts, mostly American labor, an increase of wages is granted on a sliding-scale ranging from copper at 13 cents to copper at 26 cents. The agreement is printed both in English and Spanish. It constitutes an interesting and instructive comment on the disturbances during the latter half of 1915.

Peace Rumors

Persistent talk of peace in Europe, together with the rapid enlargement of production, is having a growing effect on the metal markets. To what extent the general prosperity of the United States is dependent on war business is a question that cannot be answered definitely until an armistice is declared between the great belligerents. The Secretary of Commerce, Mr. William C. Redfield, has stated that there will be no industrial depression in this country when the War ends, and he supports his opinion by asserting that the country's war business constitutes not more than 5% of its total industrial and commercial activities. He estimates 25% of our exports as due to the abnormal conditions and points to the doubling of our shipments to South America as something independent of the War. We confess that the opinion of such an authority ought to impress us more than it does: the South American increase is a result of the War and it must represent in part, at least, a transfer of commerce that will return to its former channels, toward Europe. Even a 5% increase in any trade may be enough to exert a powerful influence on the price of a commodity. Although not nearly so well informed as the Secretary of Commerce, we believe a depression inevitable as soon as hostilities cease, if for no other reason than the disarrangement that will ensue. On the other hand, it appears to us most likely that the depression will be temporary, and will be followed by a steady increase of industrial prosperity, for reasons that have been sufficiently discussed in these pages in preceding issues. The wise man will be wary in times like these and recognize the essentially speculative features of the position. Zinc is not so high as it was for good reasons: rapid increase of production and severe curtailment of consumption in the galvanizing of iron. The increased demand for brass-making is due to the War and the decreased use by galvanizers is due to the excessive price. With a decline in one trade there will ensue a drop in the price that may, and probably will, be met to an appreciable degree by a larger consumption for peaceful purposes; but spelter stands at a figure that cannot be maintained for the simple reason that the cost of production is about one-third of the present price. As regards copper it is noteworthy that the average exports in the form of ingots, pigs, and bars during 1915 and the first four months of 1916 have been at the rate of 55 million pounds per month while in 1913 the average shipment of the same crude products was at the rate of 76 million pounds monthly. This difference is explained mainly by the cessation of trade with Germany, and

would appear to give promise of a big exportation to that country as soon as the War is ended, but we suspect that a considerable portion of the copper imported by Germany in 1913 was intended for warlike purposes, so that importation may not be resumed in anything like the same volume unless peace be regarded by Germany and her opponents as a temporary truce, affording an interval of recuperation for another contest. Of course, every sane human being will be glad to see a cessation of organized murder, and the hope is that peace will not be a mere interlude between recurrent contests on a world-wide scale. If the growing weariness of the horror induces a temporary armistice, leaving the contestants in the mood to resume as soon as they have recuperated, then peace will wear a sardonic smile and an armed truce will be followed in a few years by another Armageddon. That would mean a piling of munitions and a steady accumulation of armaments, all requiring enormous quantities of the metals produced by the miner.

Mucking as an Educator

This is the season for giving counsel to students about to commence a career in mining. Most of them will have had advice *ad nauseam* and may be pardoned if they ask to be excused from more of it. There are two reasons for giving advice, one because the other fellow wants it, the other because you feel impelled to give it to him. The impulsion may arise from hearing somebody else giving directions that appear to be quite wrong. An injunction against which we would like to enter a caveat is that concerning manual labor. More than once we have seen a scholarly gentleman waving his lily-white hands while he urged his young friends to get down to realities, to become practical, to serve the apprenticeship of toil, by working as a shoveler, driller, trammer, or timberman, preparatory to promotion as a shift-boss, superintendent, or manager. We remember discussing this subject—the advisability of mining graduates starting as manual laborers in the mine or mill—many years ago in the office of the Calumet & Hecla with four other men equally anxious to find the answer to a basic question. What the present writer thought then he still thinks and it is this, that for such graduated mining students as are sufficiently muscular and hardy to perform the work of manual labor underground it is an excellent experience if not unduly prolonged. By working side by side with the toilers on day's pay the young man can gain an understanding and sympathy with the run-of-mine workers that may prove invaluable later when he becomes a superintendent or manager. But not many young fellows can do such work as drilling, tramming, or shoveling without being so fatigued as to care only for sleep and food. When working under such a strain, their mental faculties are in abeyance, they cease to observe, and they learn next to nothing. It is a mere treadmill. We speak for the average man. Not long ago one of our friends, now a distinguished engineer, told us how he used to work with the timber gang and when the shift was over he had enough energy left to enable him to dance till the small hours; he was so strong that his work did not begin to exhaust him. For him, and a few others like him, the experience of a working miner was excellent; for it was not prolonged; he was promoted. But to the average young fellow such an experience means utter physical exhaustion and the loss of valuable time, for he learns comparatively little while at work, owing to the intense absorption in the physical performance. In some cases, the effort induces permanent loss of health. Fathers who themselves were able to serve this severe apprenticeship are prone to forget that their sons have been reared under less Spartan conditions and are not so fitted to stand the strain. Moreover, rough labor does have a coarsening effect, which may be temporary, but in some cases endures. This may seem a negligible matter, if it involves only loose speech and vulgar terms of expression, but, after all, what is the purpose of a university training if not to give refinement of mind. Much of the belief that manual labor, or a training that begins at the bottom of the ladder, is good for the young fellows is based on the fallacy that a man must do a thing himself in order to know how it should be done and whether it is done properly. That is wrong. Keen observation and logical reasoning will enable a quick-witted person to pass correct judgment on a performance that he himself could not duplicate. A familiar example of the application of intelligent observation is afforded by the golf-caddy who himself has never played the game and yet can criticize a player's method, and even suggest the right remedy, simply because he has watched scores of other players, noticing cause and effect subconsciously so as to know that certain poses or movements produce certain results in the flight of the little innocent white ball. It is not necessary for an engineer to have thumped a drill or shoved a car in order to detect whether the one kind of work or the other is being done properly. What is the purpose of a student's training in the laboratory but to develop his powers of observation and what is all his scientific teaching intended to do for him but to enable him to reason correctly from facts carefully noted? Of course, every kind of experience is useful. If the span of human life were that of an oak, we should advise the young engineer to submit himself to a course of training and development that would include every phase of mining and metallurgical activity. But time is of the essence in this matter, as in most human affairs. *Ars longa, vita brevis est.* We go so far as to say that for the average young engineer, healthy and athletic without being as tough or hardy as the sons of the soil, it would prove more useful if he devoted a year to a study of book-keeping and accounting rather than spend it as a 'mucker,' and that six months given to learning Spanish might help him more than twelve months drudgery with the shovel. Not on his biceps but on his brain does the engineer depend for effectiveness; engineering is the conquest of mind over matter.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Nitrogen Gas in a Mine

The Editor:

Sir—The occurrence at Tonopah, cited by Mr. Steidle in a recent issue of your paper, of nearly pure nitrogen as a metal-mine gas, is of great interest, but I would suggest that it may be merely an extreme case of the removal of oxygen from atmospheric air by the oxidation of pyrite, etc., as noted by J. S. Haldane in coal mines, and of which several instances have been recorded as occuring in metal mines of the Western States.

When blue clay, or slate, containing finely-divided pyritic minerals is freely exposed to air, especially in a moist and warm atmosphere, oxygen may be quite rapidly absorbed. This effect may be accompanied by a considerable rise in temperature, due to formation of ferrous sulphate, with more or less free sulphur, ferric sulphate, or sulphuric acid. In view of the large amounts of sulphates found in some mine-waters, and of the fact that a pound of pyrite would suffice to completely deoxidize 30, and even up to 60, cubic feet of air, it is easy to account for the presence of large volumes of free nitrogen in a mine containing old stopes filled with pyritic waste or broken ore. Concentration of nitrogen in this manner probably accounts for the 'pockets' of gas occasionally observed in the backs of irregular levels and stopes, as, unlike carbonic acid, this gas is evidently lighter than air, though resembling it in extinguishing a candle-flame.

A case was reported from Colorado ten or twelve years ago, where nearly pure nitrogen appeared when the barometer fell, apparently on account of the expansion of stagnant air in stopes exposing pyritic material. A continuous stream of nitrogen might result from the slow passage of air through a similar mass of broken pyritic rock, and the cases mentioned by Mr. Steidle may possibly be explained in the same way.

I was once warned against entering an old untimbered shaft that had been recently uncovered, the air being reputed poisonous, and was surprised to find that a candle was extinguished when lowered a very short distance below the surface. A day or two later the air would support a candle-flame, and it was then noticed that ferrous carbonate was a prominent vein-mineral, and that much of this had become oxidized to a soft brown mass of limonite. At another mine a candle refused to burn through a stretch of over 50 ft. in a long drift, matches could not be lit, and even a carbide lamp required great care to keep the flame burning, although compressed air was escaping near the face of the drift. The dump of soft ore from this drift was found to be steaming from the heat due to rapid oxidation of pyritic shale, and was intensely hot a foot or two beneath the surface.

Hoover's 'Agricola' contains a reference (page 210) to Pliny's observation of the fatal effects of the vapor arising from "sulphuretted" or "aluminous" rock in deep wells, and details of several cases are given in Pryce's 'Mineralogia Cornubiensis.' Probably these, as well as many of the reported occurrences of alleged poisonous gases in old cellars, etc., are attributable to shortage of oxygen from absorption by pyrite, etc., rather than to any actual evolution of noxious gas. Even when carbon dioxide is found in the air of metal mines, apparently as a natural product, it is no doubt often due to the reaction between calcium carbonate and sulphuric acid or iron sulphates resulting from oxidation, as has also been pointed out by Haldane.

With regard to the occurrence of nitrates in mine-waters, I would like to ask Mr. Steidle if it is quite certain that these may not have been derived from explosives. In one case, reported in *Science* some months ago, the water of a deep well was condemned on account of the alarming proportion of nitrate it contained, until it was found to have been 'shot,' on the completion of drilling, with a large charge of dynamite. On the other hand, large percentages of nitrates have been found in the residues from various natural waters, and several analyses of such residues are given in F. W. Clarke's 'Data of Geo-Chemistry.'

W. J. Sharwood.

Lead, South Dakota, May 1.

Inventors and Their Reward

The Editor:

Sir—In a recent editorial on the subject of patents, you state that "the end in view is the rewarding of the inventor, without creating an incubus on industry." If we were only certain that this was the end in view, half our troubles would be over. Unfortunately that group of the public interested in patents, does not have only that end in view, namely, "the rewarding of the inventor," and in many cases it is the last thing thought of. The variously interested groups have different objectives, which might be roughly designated as follows:

The inventors are almost as much absorbed in the joy of the creative as in the possible perspective of the rewards that they seldom get. The attorneys, as a rule,

look upon the inventor as a fit subject for fees, and stimulate any kind of invention, however worthless, so long as it is patentable and subject to fees. The Patent Office looks upon the inventor as a kind of spool, upon which to wind unlimited red tape. The capitalist looks upon him as a sometime creator of useful monopolies. The average manufacturer looks upon the inventor's brains as a species of unprotected public store-house to be looted whenever possible. And the rest of the public considers the inventor a poor crazy fool, a crank to be pitied and derided.

In view, as you express it, of this 'low state of public morality,' far-reaching reforms should be demanded. The inventor is rarely considered in his true relationship to our complex civilization: he is the fountainhead of all material progress in the arts, sciences, and industries.

Our Patent Law and the Patent Office should be society's embodied expression of approval and encouragement for the inventor. Means should be found to give him useful criticism and suggestion, as well as technical and financial support.

The present law is supposed to supply a man with title to a thing that is essentially his. In the case of a homestead or any other form of property, the Government does protect him, and is particularly careful to avoid giving title to the same piece of land to two or more men. In the case of a patent, the Patent Office appears to be in the habit of issuing (of course quite unintentionally) titles to several different parties for that which the courts afterward declare to be identically the same invention.

Mr. Prost claims that monopoly is prevented, because price, supply, and demand are always automatically self-regulating, on a just basis by natural law. Let us see if this is true: an example taken to the extremes of absurdity is often the best way of analyzing fundamental principles. Allow me to assume that I invent successful processes and machines, with the special object of mining and treating very low-grade copper ore, and that I am fortunate enough to obtain unquestioned basic patents: and that with these inventions I am able to produce 5c. copper from deposits previously unworkable; and further suppose that I had great capital at my command, and I bought up a number of these deposits, to a sufficient extent to supply the world's immediate demand, and then started to produce an unlimited amount of 5c. copper, and at the same time refused to give a license for my patents to other copper producers. Would I have a monopoly, and without interfering with the prior art, and would my low-priced supply of practically all the demand unjustly affect the other producers or not? Furthermore how long would it be before almost every producer would be on his knees, willing to enter into almost any kind of contract, control, or combine that I liked to stipulate; and if the spirit of John D. was in the ascendancy, how long would it be before I made the general public pay 30c. of which to give the producer 10c. and keep 20c. for my well-earned recompense, perhaps reserving a cent or two for educational foundations. Some of our monopolies have developed into veritable incubuses, a burden to the American nation and a menace to the stability of our present state of society, because they have produced by reflex a dangerous discontent among the exploited class.

In the matter of stimulus, the present system is too difficult to admit of many meritorious inventors registering their ideas. While doubtless many worthless ideas are put forward, conversely, many valuable ideas remain buried, and in some cases are lost. There is also no method by which good ideas, once patented, can be brought into the limelight. It is assumed erroneously that the inventor will be able to place his ideas on the market once a patent has been granted. This is not the case, and the inventor is not the only loser. The public has a great interest at stake. If the flotation process had been developed when the first idea was sent to the Patent Office, the world would be richer by many millions of dollars worth of lead, zinc, and copper that in the form of sulphide slime have gone irrevocably beyond the tailing-pile.

The patent as granted is only a temporary monopoly given as a possible reward if the inventor is fortunate enough to know how to protect his rights, and can make use of his patent commercially. His invention may be the inspiration for a whole series of others, which owe their existence to the original, and are merely developed and improved copies, but which surpass it from a practical and commercial point of view. If, as commonly happens, the original patent was defective from a technico-legal standpoint, the pioneer generally gets no reward, but others and the public reap the harvest. This is such a well recognized fact that it often acts as an actual deterrent to many inventors; which goes to show that the present system does not provide the proper stimulus or reward for endeavor.

With regard to monopoly, we must note a curious fact; land when required for public utility can be condemned and sold, but a patent, however much it influences a public utility, cannot be condemned, at least so far as I know. Conversely, we find an anomalous condition in comparing property and patent rights. A man does not create a piece of land, but once he obtains title by purchase or otherwise, it is his or his heirs in perpetuity. A basic patent is dependent upon the creative genius of an inventor, he produced it, it is more his than a child belongs to its mother, the sense of possession and personal ownership is far stronger than in the case of land, and yet we begrudgingly give the inventor an uncertain and temporary title to the right to make, use, or sell. Real ownership in perpetuity is never granted; why should land rights be forever sacred and an inventor's creation excepted?

Some of your correspondents evidently think that the present patent system is perfect; in fact, they want no change. You, sir, can see that "the excessive demands, not of the inventors themselves, but of patent-owning corporations, have awakened a keen feeling of protest against the whole system, causing a set of conditions detrimental to metallurgical initiative for example," and you state: "thus it is claimed, a proper reward rarely

comes to the inventor himself, but to a patent-owning corporation, which waxes rich on royalties." You add: "the conclusion is that no other method is available, and no other is needed as yet." Then you contradict yourself by saying "America is a nation of inventors: we must have a liberal patent law." Here I do not agree with you, and, in another letter I propose to outline a scheme for a reform in patent law, but let us have some discussion first. Before proposing reforms, we must have a clear conception of the fundamental principles of law and of the desideratum that we wish to obtain by means of the said law. For my part I would postulate that the fundamental principle of all law is, that there shall be a definitely understood relationship between man and man regarding the objective under consideration, and that this relationship shall be clear and definite, and upheld by some social force. Secondly, that the question of clarity not only as to the relationship *per se*, but as to its reciprocal quality, must be defined: that is, are advantages or preferential conditions always to be assured to one side as against the other, and are the said conditions to be voluntary, or are they enforced by one and passively accepted by the other; in plain language are advantages to be given to the few at the expense of the many? Is the greatest good of the greatest number to be the desideratum?

It is the clarity and the certainty of law, and the assurance of its enforcement by overwhelming strength, that gives it its great social value, and makes the mass of the human race willing to submit to much that otherwise is merely onerous. The present status of the Patent Law fails entirely in clarity, in certainty, and in the enforcement of protection. Hence our demand for reforms. In suggesting reforms, it is also well to remember that we are dealing with human qualities as well as machines, and I therefore wish to draw attention to the psychological aspects by postulating:

(1) That the human mind is constantly striving to be creative, and that it requires not only knowledge of the prior art, but a certain individual faculty, and—above all—propitious times, circumstances, and surroundings, to produce the best from creative minds in whatever line, whether art, literature, abstract scientific research, or mechanical invention.

(2) That the creative faculty is different from the constructive, although they overlap and are inter-dependent. The former is the attribute of the inventor, the latter of the engineer.

(3) That men and women equipped with these faculties are rarely commercial or aggressive, and can only be stimulated to their best endeavor by suitable environment, freedom from financial care, and that supreme comfort that comes with the knowledge of successful and appreciated achievement. Owing to the inadequate supply of these requisites, the public is not gaining the effective results that might be obtained from the inventive and constructive class in society.

(4) That, as the facilities and comforts of modern civilization are due to the creative mind, it is to the immediate interest of the public, although they do not appreciate the fact, to see to it that opportunity is provided for those of creative mind to exercise their faculties; and that during the exercise they shall be protected. Means must be found to provide the best environment for those that prove their merit, and with it a just apportionment of reward.

We must endeavor to formulate a new law without an "unnecessary interference with industrial initiative," and without waiting for the "millenium" or for "paternalism to the *n*th degree," and to accord with "unanimous public sentiment" as expressed by the general trend of our customs and laws. In formulating this new law we have to find a common meeting point for the artist of creative instinct, the man of constructive ability, the financier, the manufacturer, the consumer, and the general public.

We may postulate the desirability of an objective relationship between the nation and the inventor, and assume that if the general public had the law-making power in their hands, and if they understood the problem, and the direct importance to their own interests of a reform in the Patent Law, they would demand at least the following basic points:

A. To assure the greatest good to the greatest number.

B. That creative endeavor shall be duly stimulated and protected, and justly rewarded.

C. That the product of invention shall be promptly tested, and brought to use when meritorious, for the benefit of the public as soon as possible.

D. That suitable institutions shall be provided to assist the inventor in his research.

E. That unrestricted monopoly shall not be allowed, especially when it is detrimental to further endeavor, research, and discovery; for as the editor says, "we recognize the advantage of having ingenious men on the alert to discover improvements."

F. That the registration of new ideas shall be free.

JOHN M. NICOL.

San Francisco, April 19.

Aids to Success

The Editor:

Sir—It is interesting to consider the points that you discuss editorially on this subject in the issue of May 20. As you say, 'success' is interpreted in various ways, according to individual philosophies. With some men, success in mining means the accumulation of enough money to enable a retirement from all contact with mines, on a quiet farm in the hills; to others, success means a pyramiding of wealth beyond their capacity to enjoy it intelligently; still others strive for an honorable prominence in their profession, accompanied with a comfortable financial recompense.

A recipe for success was contained in the columns of *Life* not long ago. It gave a dozen rules how to get there. Each alternate rule contradicted its predecessor. No. 1. said: "Get a college education and fit yourself properly." No. 2 said: "By no means go to college;

such an education isn't practical." I think this article was correct, for it is only necessary to look around to see every kind of success achieved in ways that contradict all the so-called practical advice that is meted out to young men.

One general principle of advice to young men has been a favorite for years. The gist of these guidances, variously expressed, has been to "do it now," and the result has been to make a nervous strain for seeming to do something, rather than to really do anything. When I was graduated from college, some six years ago, I had the opportunity to call on a prominent master of finance in New York. I had expected that all captains of industry, such as he, were nervous hurried individuals whose business hours were one tremendous excitement. To my surprise I found a quiet deliberate man, who was as unthurried, unhurried, and human as though he never had heard of "do it now." He had no great stack of papers on his desk, and he took his time about things in a way that indicated he believed in the value of cool thinking, not bluster and bluff. While the philosophy of the strenuous life, as advocated by Col. Roosevelt and others, has done wonders for this country, I know personally several capable young men whose work has deteriorated in quality because they allowed the desire for shallow and showy results—in other words, an overdoing of the do-it-now principle—to crowd out the real merit that they could have achieved. When immediate results are demanded, superficial results can be expected. A glib man of the 'grand-stand' variety rarely thinks deeply enough to produce anything worth while. Exhibitions of energy of the sort that are minus all sense of proportion and brains, have fooled a great many people in the past, but I think the market for this coarse work is going out of style.

President Wilson in his little book, 'When a Man Comes to Himself,' suggests that a man will accomplish most in the end by following his enthusiasm, rather than being guided by necessity. Perhaps there is something to this simple bit of advice, for not always does "the four-flush take the pot from a moderately good hand."

P. B. McDonald.

Berkeley, May 25.

Cost of Drift-Mining

The Editor:

Sir—Drift-mining for some reason has taken a back seat and it is not often that we are able to make any comparisons as to costs, so these figures are given with the hope that they will prove useful to others. They represent practically 1000 shifts underground and have been carefully compiled from daily records kept at the Nugget mine (in Butte county, California) during operation. The average width of the heading was 10 ft. by 6 ft. high, this size being carried for the purpose of extracting the best of the gravel. As the gravel was about 3 ft. thick some bedrock and a little capping was taken in order to give working-room. As the bedrock carried some gold it was recorded as 'gravel.'

The work was done under favorable conditions, as an incline had to be sunk, entailing hoisting and pumping of water. All the work was done by hand, drilling in bedrock and moiling in gravel. The total cost per ton mined, $2.85, is high, in fact, about as high as this class of mining runs. The cost per foot was more favorable as many think this work cannot be done under $10. The cost, $6.35, shows what may be done.

The details are as follows:

Length of tunnel (10 by 6), 1151 ft. (inclined).

Labor, 990 shifts at $3	$2,970.00
Dynamite (40%), 2319 lb. at 16c.	371.04
Detonators (6X), 3157 at 1c.	31.57
Fuse, 9096 ft. at 65c. per 100 ft.	59.15
Candles, 1989 at 10c. per 6	33.15
Total	$3464.91

Feet of holes drilled, 6270.
Cars hoisted, 3416 at 1500 lb. = 2562 tons.
Mining cost per ton = $1.35.
Mining cost per foot = $3.01.

Timbering:

Labor	$ 80
Timber	21
Lagging	16
Wedges	6
Total	$123

Cost per ton = $0.048. Cost per foot = $0.1068.

It will be noted that little timbering was necessary, boulders being used for filling.

Other costs were:

All equipment	$1960
Power	168
Top labor and superintendence	1600
Total	$3728

Cost per foot, $3.23.
Cost per ton, $1.45.
Total cost per foot = $6.35.
Total cost per ton = $2.85.
Tons per shift = 2.58.
Feet advanced per shift = 1.16.
Two men on each shift.

The total cost of the equipment in this case was charged to mining, as the equipment all reverted to the owners of the mine when the operating company ceased operating. As all the equipment was well taken care of, it would only be fair to allow it a cash-value of 60% of its cost, which would reduce the total cost of mining to $2.3965 per ton, and footage to $5.3257.

Where a total gravity system can be used the cost of drift-mining should be cut to approximately $1 per ton for gravel, and from $5 per foot upward, according to size and hardness of headings.

J. D. Hubbard.

Magalia, Cal., April 15.

Arizona had only 49 men killed around mines in 1915, as compared to 62 in 1914, yet the number employed was much larger in 1915, being 13,598 as compared with 9422. The fatality rate for 1915 was 3.6 per 1000, which is not a high proportion.

The Dry Chlorination of Complex Ores

By S. A. Ionides

THE PURPOSE of this process is the extraction of all the metals in an ore, their purification, and reduction to metallic form. It was devised primarily for the handling of complex sulphide ores containing zinc, such as could not be treated profitably by any other means. The main development took place in Montana some seven or eight years ago, the experiments carried on by John L. Mahn for the late F. Augustus Heinze reaching a stage where the latter was preparing for the erection of a $2,000,000 plant, when the crisis in his affairs caused the project to be dropped. The work languished until 1914, when the Bunker Hill & Sullivan Mining & Concentrating Co. nearly completed a plant at Kellogg, Idaho, and it is unfortunate that their lack of perseverance robbed them of the success they deserved.

THE FLOW-SHEET. Prior to treatment with chlorine gas, the ore must have been dried and crushed to a point where at least one facet of each particle of mineral is exposed. How far the crushing must be carried to meet this condition depends on the nature of the ore, but in no case need it be as fine as for concentration, where each mineral particle must be isolated.

The treatment with chlorine gas can be effected best in a tube-mill as illustrated in Fig. 2 and Fig. 3. The chlorine enters at the ore-discharge end and promptly attacks the sulphides of the metals, converting them in part into chlorides. The extent of the conversion depends both on the ore and the temperature. With some ores the reaction will start at ordinary atmospheric temperatures, but if left uncontrolled the temperature will rise to an undesirable extent and the sulphur set free by the reaction in its native form will melt and, if present in sufficient proportion, agglomerate the whole charge.

With other ores, especially those low in sulphur, it may be necessary to heat the charge to 100°C., or even to 150°C., to start the reaction and carry it forward.

It is usually advantageous to carry the chloridization

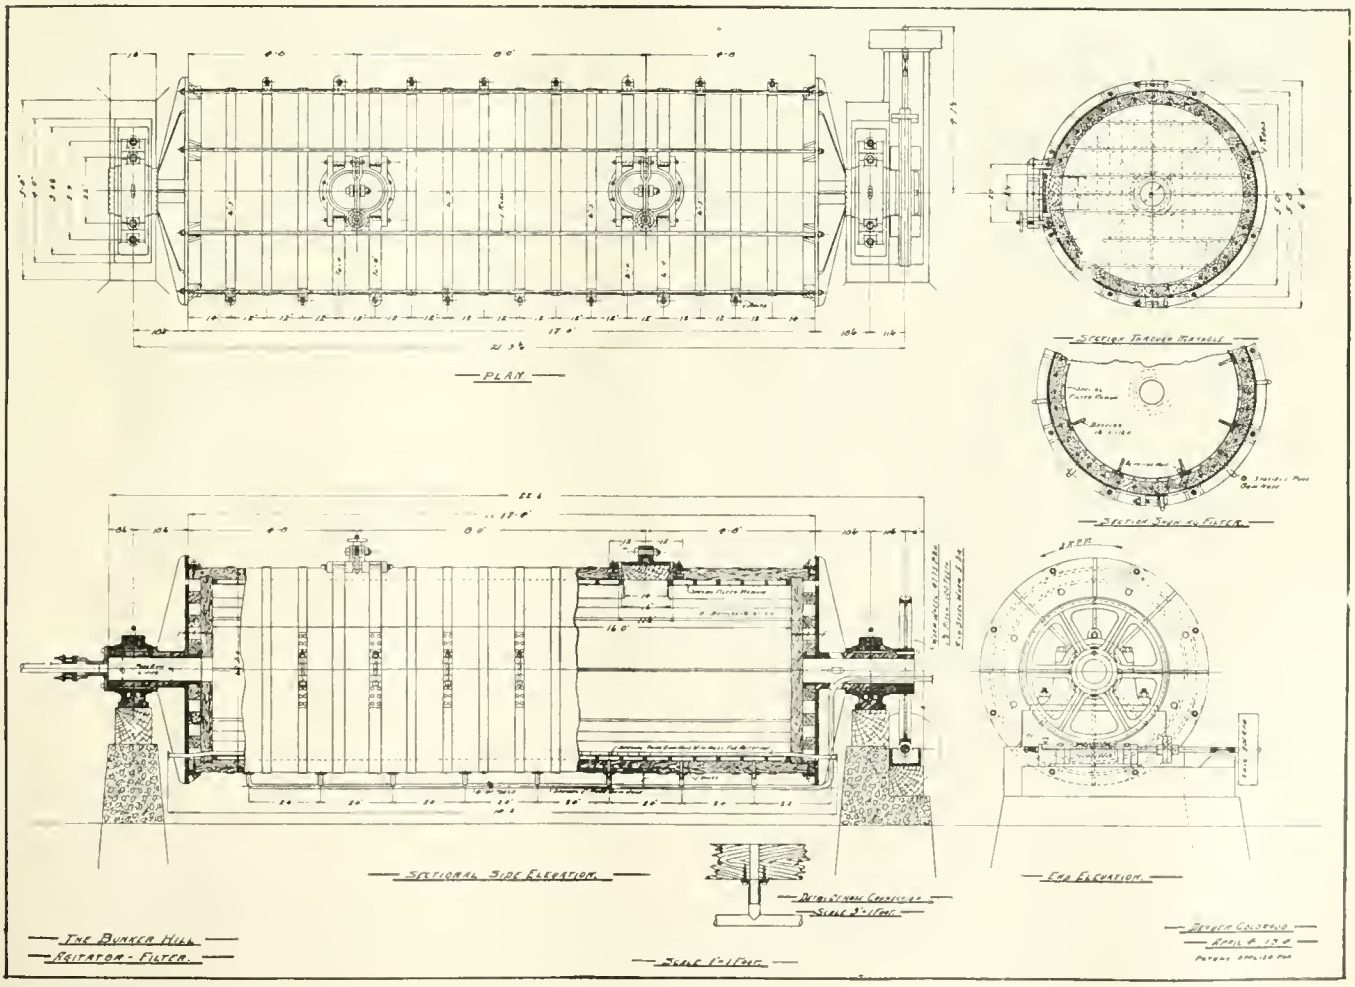


FIG. 1. THE BUNKER HILL AGITATOR-FILTER.

to a point where from 40 to 70% of the metals is in chloride form. The reason for this is that in every ore there is more or less iron, which becomes converted into chloride, and in the subsequent treatment the iron can be made to yield its chlorine to other more valuable metals.

The second step consists of subjecting the ore to a mild chloridizing roast, the salt in this case being the ferric chloride already formed, which in the presence of air and metallic sulphides is decomposed with the formation of ferric oxide and metallic chlorides, thus completing the reaction that was started in the tube-mill. This reaction can be carried out effectively in a multiple-hearth roasting furnace by feeding the partly chloridized ore onto the third hearth and dropping it through the lower hearths, using the two upper hearths to catch the excess of chlorine given off either as such or as hydrochloric acid gas from the decomposition of the ferric chloride and which may have escaped contact with the sulphides in the lower hearths. For this purpose fresh sulphide ore is kept circulating through the two upper hearths.

The third step is the dissolution of the chlorides and their separation from the gangue. This obviously suggests agitation and filter-pressing. The Bunker Hill agitator-filter (Fig. 1) was specially designed for this purpose. It is fully described later.

The solution leaving the filter contains practically all the metals in the ore in the form of chlorides with the exception of iron, most of which has been converted into ferric oxide and so rendered insoluble, and the precious metals, which may have remained insoluble or have been precipitated if any reducing agents are present.

The gangue, which has been thoroughly washed by steam following the discharge of the solutions, is then run over amalgamated plates to catch any precious metals, and thence to the dump.

The fourth step is the separation of the metals in solution. As there is far more room for variation at this stage of the process than at any other, a definite ore will be considered, say, one containing the following metals: Cu 0.5%, Zn 2.5%, Pb 9.0%, Ag 3.0 oz., and Au 0.05 oz. This ore has been chosen as being of more general occurrence than the slime treated at the Bunker Hill, which contained Zn 2.5%, Pb 11.0%, and Ag 4.5 oz., and was practically free from copper and gold.

In this case a fractional system of dissolution would be employed. The first wash would consist of a charge of two tons of hot mill-solution to each ton of ore, as little wash being used as allows the agitation to be effective. The mill-solution built up from previous runs would contain the chlorides of iron, copper, and zinc, some silver chloride and its burden of lead chloride. It would dissolve practically all the iron, copper, and zinc chlorides, all of which are freely soluble in water, the silver chloride, which is soluble to a moderate extent in hot solutions of the chlorides of other metals, but only a little lead chloride, owing to the burden that it carries already and to the fact that lead chloride is less soluble in solutions of other chlorides, except salt, than it is in water. The gold will be dissolved only if all the iron in solution is ferric chloride.

The second wash would be similar to, but weaker than the first. Its purpose is to build up a new first solution to replace the latter when it becomes burdened and is passed for further refining, at the same time removing the last of the iron, copper, and zinc chlorides from the ore.

The third wash would consist of a boiling hot concentrated solution of common salt, which is a good solvent for lead chloride. This wash, instead of being pumped back to its own storage-tank, as with the other two washes, is run into a shallow cooling-tank, where the lead chloride rapidly crystallizes. From there the crystals are passed to the lead chloride collector, where they are washed with cold water, collected, dried, and charged into the lead-chloride melting-furnace, where they are fused and run into the lead electrolytic cells.

The first wash with repeated cycles becomes stronger till it reaches its saturation point of silver chloride or the zinc chloride reaches a concentration of 50% or more, when it is ready for further refining. This consists of precipitating the iron as oxide with zinc oxide or carbonate and replacing the various metals by one another, silver and gold by copper, copper by lead, and lead by zinc, so that the final solution contains only zinc chloride, which is then ready for evaporation, fusion, electrolysis, producing zinc of the highest quality and regenerating the chlorine for use in the tube-mill.

If other metals were present they would be removed in the same way, as any metal will precipitate from solution all metals, with few exceptions, the salts of which have a lower heat of formation. A separation of almost any combination of metals in solution can be effected in the same way by replacing them consecutively one by the other in the order of the heat of formation of their salts. An exception is manganese; but it can be precipitated at the same time as iron by zinc oxide if a current of chlorine gas be passed into the solution. The metals after precipitation are washed, dried, melted, and cast into bars.

The most vital step in the whole process is the electrolysis of fused zinc chloride. A great deal of thought and attention was given to its development by the electrical staff of the Bunker Hill company.

The type of cell used was that developed in the early work in Montana and the experiments were concentrated on finding the most satisfactory form for the electrodes. The result of these experiments was the cell illustrated in Fig. 4, the design of which was due to Malm.

Model Arrangement. This sketch, Fig. 3, was made on the basis of the plant installed at the Bunker Hill, but the arrangement shown here is on a one-floor plan, while the Bunker Hill mill was on two floors. The purpose is to show the straight-line arrangement of the tube-mill, evaporators, and electrolytic cells, thus allowing easily for additional capacity as needed and more particularly to illustrate the course of the chlorine gas. The mention of a chlorination treatment is apt to suggest the idea of large volumes of a very undesirable gas and the

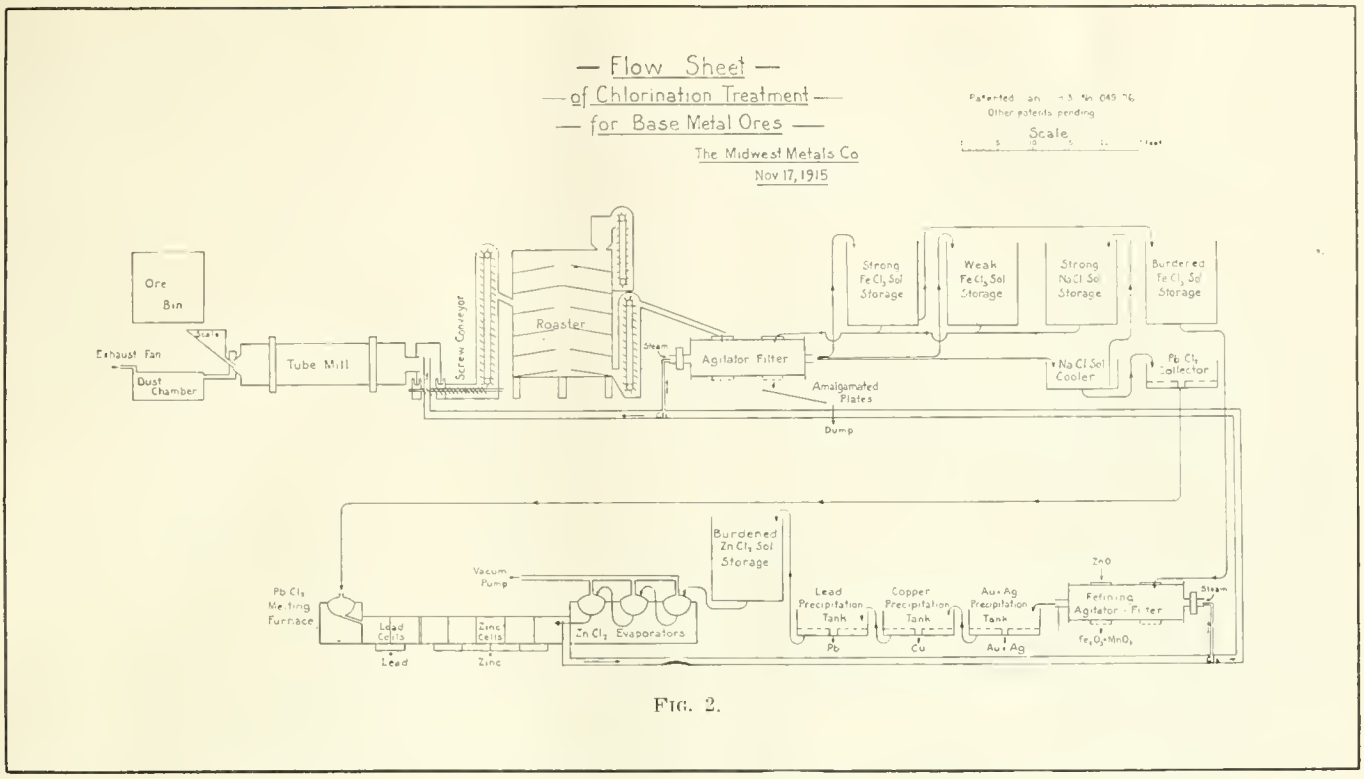

Fig. 2.

question is naturally raised as to what is done with all the gas and how it is controlled.

The following figures and the model plan answer these obvious questions. With 4000 amperes the capacity of each cell is, in round figures, 250 pounds of chlorine (and 250 lb. zinc or 750 lb. lead) per day. From each battery of 20 cells the output will then be 5000 lb. chlorine per day. At 0° C. and 760 mm. pressure 5.05 cu. ft. of chlorine weighs 1 pound, hence there would be generated, in round numbers, 25,000 cu. ft. of chlorine per day, or 23.3 cu. ft. per min., if the gas were at 0° C. and 760 mm. pressure. With the gas at 450° C. this volume would become 61 cu. ft. per minute, or, say 1 cubic foot per second. The pipe leading from the cells to the tube-mill is about 40 ft. long and 1 ft. diam. The cross-sectional area of this is 0.78 square foot, which would give the gas a velocity of 1¼ ft. per second, a very modest velocity.

The pipe at the Bunker Hill proved perfectly satisfactory; it was made from vitribestos board (an asbestos

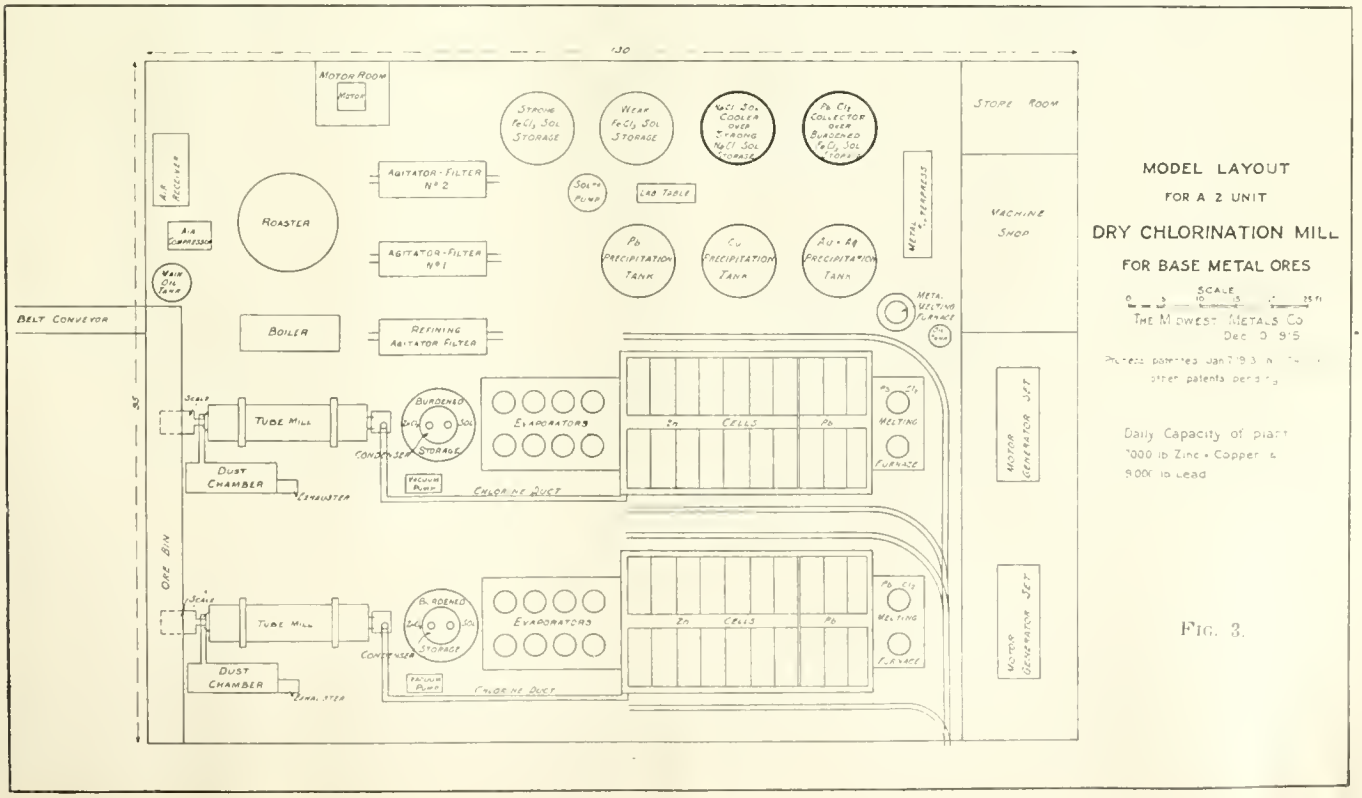

Fig. 3.

product, and to ensure that there be no leak of gas the whole pipe was kept under suction by setting an exhauster on the far side of the tube-mill, as shown in the flow-sheet. This was an advantageous position for two reasons: the exhauster was kept out of contact with the chlorine gas, which was completely absorbed in the tube-mill and, by reason of this absorption, its duty was reduced.

Construction of Cells.—These cells for fused zinc chloride were cast in a battery of 20, ten on each side of a central duct. The frame was of concrete and lined throughout with fire-clay tile. The main features of the cell were the electrodes. The anode measured 30 by 62 in. and was built up solid to the required size from graphite blocks. Numerous small holes were drilled through it to allow for the ready passage of chlorine gas. The dimensions were designed for a current density of 500 amperes per square foot and the length was extended sufficiently to allow it to project through the front of the cell, enabling proper electrical connections to be formed. The anode was supported 1¼ in. above the bottom of the cell by porcelain insulators and was packed tight into its recess in the wall.

The cathode consisted of molten zinc covering the bottom of the cell to a depth of ¾ to 1¼ in. Across the centre of the cell was a well 6 by 6 in., which also extended through the wall to allow an electrical connection to be formed outside the cell.

The tapping system was ingenious. The tap-holes were half-inch holes drilled lengthways through 1½-in. round graphite rods that projected through the front of the cell. They were filled with zinc, which solidified in place and formed an effective seal. When ready to tap, the projecting end of the graphite rod was connected to the anode by a short length of copper wire, terminated by a plug that fitted into a corresponding hole in the anode. This short-circuited the whole of the current through the graphite tap, which developed sufficient heat to melt the zinc seal promptly. When the proper amount of metal had been drawn off, the connection was broken and an asbestos plug inserted in the end of the tap-hole until the zinc within had solidified and so re-made the seal.

In operation, the cells were thoroughly heated and molten zinc poured in, a temporary form being set outside to make the connection. The anode was then packed into place and the electrical connections completed.

The cell was again heated thoroughly so that the zinc cathode was molten and there was no chance of chilling the fused zinc chloride. This point is of great importance, because while the fused salt is a conductor, the solid salt is a powerful insulator and if a skin chilled round the anode, it would be impossible to force any current through.

As soon as the cell was heated sufficiently, the fused electrolyte was run in and the current turned on. If the heating had been sufficient, electrolysis would start at once with a high voltage, which in the course of a few hours would drop to normal.

If the zinc were not molten at the start, the result would not necessarily be serious, as with running, the temperature of the cell could be forced up to melt it. However, it is not good practice to start with the zinc solid, as splashes may have formed on the walls while it was being poured in, and these points being nearest to the anode would build fastest and might form a short circuit.

For continuous operation, of course, it is essential that the zinc be kept molten, so that it can be tapped. If the temperature is kept too low, the zinc is deposited in pellets, which accumulate and in time short-circuit the cell. If this happens, the only remedy is to shut off the current, open the cell, and apply heat from outside.

A good working temperature is 480° to 550° C., which is comfortably between the melting-point of zinc (420°) and the boiling-point of zinc chloride (730°).

The chlorine gas is drawn off through the ducts shown in each cell into the central duct and thence through a pipe under the floor to the tube-mill, where it is promptly absorbed.

The Chart (Fig. 5) shows the readings taken on three days' run of a 1000-ampere cell and illustrates the control that can be maintained. The run was made for this purpose, various experiments being tried, such as charging the cell rapidly with barely fused zinc chloride, which naturally reduced the temperature in the cell. The sudden drop in the ampere record can be seen following each fill; and the quicker the fill, the greater the drop. Under these conditions high efficiency could not be maintained, but the metal deposited during this run of 110 hours was found to be 85% of the theoretical deposit calculated from the average amperes used.

With steady working conditions, which consist of a steady current, continuous feed of fused electrolyte at the cell temperature, and tapping at regular intervals, a regular curve would be obtained as shown at (D), on September 14, from 6 a.m. to 12:40 p.m. During that time the voltage was kept constant and as the zinc was deposited, the space between the electrodes was reduced, the resistance being diminished accordingly and the amperes increased. The temperature dropped a little and then remained constant around 480° C. for the last two hours of the period.

On changing conditions, the following normal course may be expected: On change of voltage, the amperes will follow in the same direction and with more of a lag the temperature will follow suit. This is shown on various occasions, as at (B), on September 13, from 5 to 7 p.m. and on the last 12 hours of the chart.

The effect of the addition of cool electrolyte is shown clearly at (E), on September 14, at 2 p.m., when the sudden addition of electrolyte produced a marked dip in the ampere curve; at (C), on September 14, at 1 a.m., when the feed being hotter produced less dip; and at (A), on September 12, at 11 p.m., when its gradual addition produced considerably less disturbance.

The effect of tapping is in the same direction as the addition of cool electrolyte, but it is not nearly as marked. It is sufficient, however, to warrant the effort to keep the space between electrodes as short as possible.

FIG. 4.

The chart is unfortunately incomplete in that the temperature of the electrolyte when fed was not recorded, nor are the figures for the voltage absolutely reliable. This is owing to external resistances, which were not accurately measured. These resistances would, of course, have no effect on the form of the chart, but would affect energy efficiency.

Charts were made on other runs, one of which extended over three weeks, the results confirming those illustrated here. Two shut-downs are shown by breaks in the lines of the ampere and volt curves. On each of these occasions the cell was started again with a high voltage and low amperage but quickly came back to normal conditions. Later a shut-down lasted for six hours after which the cell was re-started without trouble.

Bunker Hill Agitator-Filter. This combined agitator-filter consists of a cylindrical barrel 16 ft. long by 5 ft. diameter. It was constructed of wooden staves set lengthways against cast-iron heads. The barrel was banded with flat-iron bands set 12 inches apart. The heads were held together with 8 bolts, which also served as truss-rods for supporting the staves. The inside of the heads was lined with wood, through which communication to the inside of the barrel was made at one end, but not at the other.

The whole of the inside of the cylinder was lined with cocoa matting and inside of that again was set asbestos filter-cloth. The filter-cloths were in 8 sections and were held in place by the same number of baffle-boards, which were wedged into place in slots built to receive them. The baffles were set longitudinally to agitate the pulp in the barrel as it was rotated on its axis. Two man-holes served for the admission of workmen to fit up the inside of the barrel, and for the subsequent charging of the ore and discharging of the tailing. All internal fittings were made with wooden dowel-pins, as the corrosive nature of the solutions rendered the use of iron nails impracticable.

The discharge of the solutions is through externally fitted rubber hose, eight in number, which are kept separate until united at a common header in the trunnion at the blind end of the barrel. This allows each section of the filter to be tested separately and leaky sections to be replaced with a minimum of disturbance. One of these hose-lines is shown at the bottom of the barrel in Fig. 1.

The open end of the barrel has connections for admitting steam, compressed air, and chlorine.

In operation, the barrel was half-filled with hot strong mill-solution and the ore from the roaster was charged through one of the man-holes. These were then closed and the barrel revolved. When sufficient agitation had been given, steam under pressure was admitted. The barrel was designed for a maximum pressure of 25 pounds, but the full pressure was rarely necessary to form the cake. The steam heated the solution and at the same time forced it out through the hose arranged for its discharge and following the solution, gave the cake a thorough wash. On release of the pressure, the cake peeled off, due to the sagging of the filter-cloths, and the second wash was admitted through the open trunnion-end while the barrel was revolving. The procedure was the same with the second wash, and on its discharge the third wash was admitted. This was the salt wash for lead chloride. At this point one of the particularly strong features of the agitator-filter was demonstrated. The admission of steam under pressure raised the temperature of the pulp above 100° C., which materially increased the solubility of lead chloride in salt solution, so that the steam following through after the wash cleaned out the last traces of that difficultly soluble salt.

To discharge the residue, the cake was churned with water, the man-holes were opened and a few revolutions of the barrel were sufficient to empty it.

To make a dry discharge, compressed air was turned on for a few minutes, the pressure allowed to fall, the man-holes opened, and, the cake peeling off, the filter soon dropped through the man-holes as the barrel was revolved.

The regular charge was 4 tons of roasted ore, which was reduced to 3 tons by the dissolution of the soluble constituents, and formed a 2-inch cake, the regular practice.

The Chemistry of the tube-mill and roaster reactions has not been completely worked out, though the results are known. Taking 'M' as a di-valent metal, such as lead, zinc, or copper, the tube-mill reactions in all probability are:

$$MS + 2Cl_2 = MCl_2 + S_2Cl_2$$
$$MS + S_2Cl_2 = MCl_2 + 2S$$

or combining the two equations,

$$MS + Cl_2 = MCl_2 + S$$

All three reactions probably take place simultaneously in the tube-mill. In presence of moisture some side reactions occur, such as:

$$MS + 4Cl_2 + 4H_2O = MSO_4 + 8HCl$$

The formation of sulphates has been observed in the tube-mill product when the temperature has not exceeded 70° C. It would seem likely that the presence of sulphates would hinder the extraction of lead, as lead sulphate is almost insoluble in water, but it has been found that when boiled with ferric chloride or sodium chloride, lead sulphate is decomposed with the formation of lead chloride and the sulphate of iron or sodium. For this reason the formation of sulphates does not interfere with the extraction of lead.

This reaction offers an alternative method for introducing chlorine into the mill system to replace wastage by taking the chlorine, as indicated, from salt in place of buying zinc chloride, which is the normal course and which would be used in starting the mill. It also offers a basis for a method of treating lead ores without electrolysis, particularly where salt is available at a low price.

These reactions do not depend on the use of pure chlorine gas, though in certain cases the use of nearly pure gas may be advantageous. During the early work in Montana the gas was obtained from the electrolysis of aqueous solutions of salt and contained from 3 to 5% of chlorine. The gas from the electrolysis of fused zinc

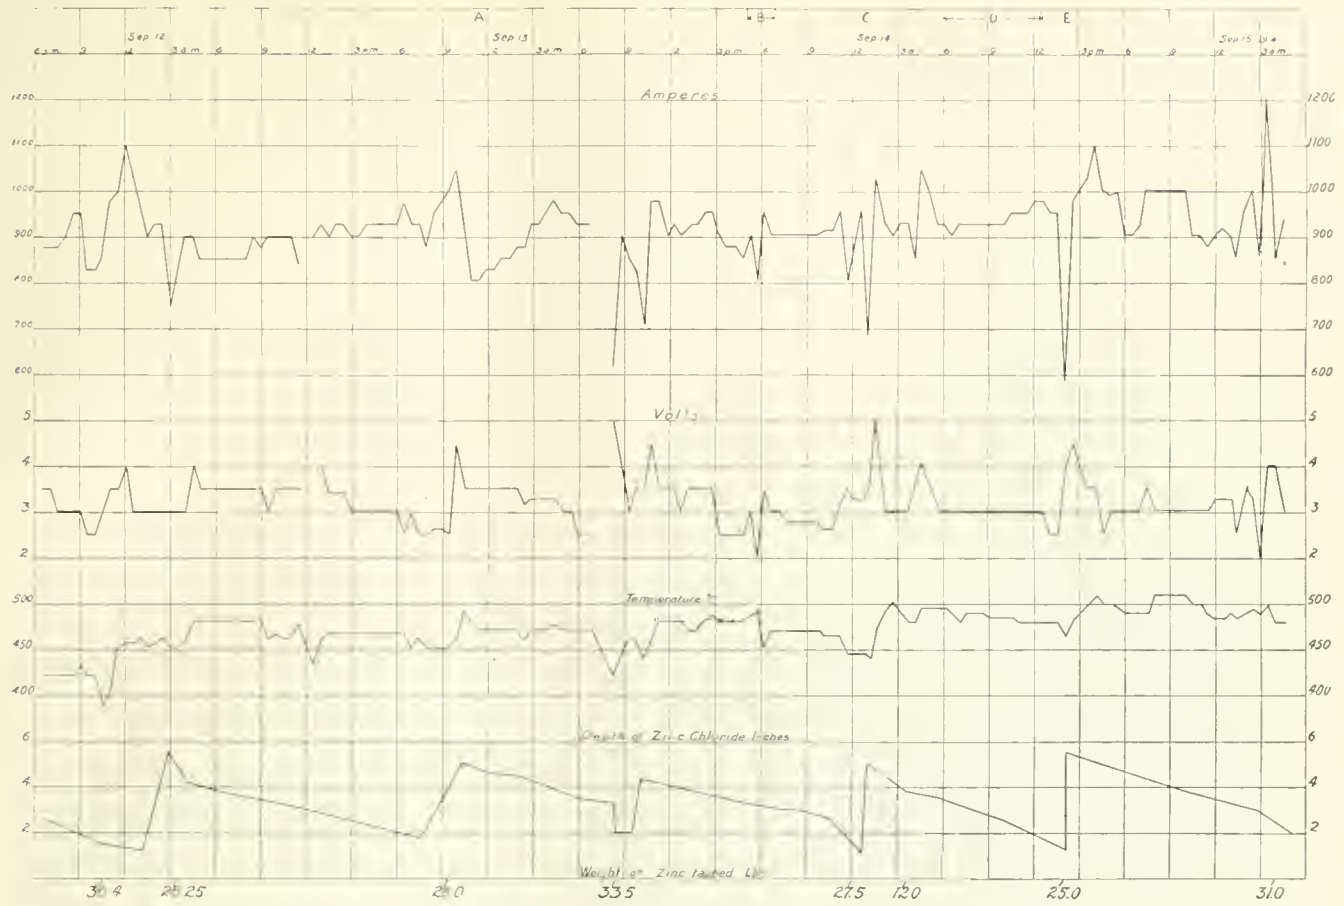

Fig. 5. Chart of 1000-ampere cell run.

chloride can be obtained as nearly pure as desired.

Similar equations to the above could be shown for metals having other valencies than two, such as ferric iron, which is tri-valent and silver, which is mono-valent. Their behavior is strictly analogous.

The formation of sulphur chloride can be demonstrated readily on a small scale. If the tube containing a charge of sulphide ore be heated above the boiling point of sulphur chloride, say to 150° C. and chlorine admitted, the sulphur chloride can be distilled over and condensed as a dark-brown liquid, which is promptly decomposed by water with the liberation of part of the sulphur in its plastic form.

Under similar conditions with an ore containing arsenic and antimony, the chlorides of those metals were distilled over and condensed.

As a rule carbonates are not attacked in the tube-mill. However, at Bunker Hill it was found that siderite (ferrous carbonate) in presence of chlorine, air, and moisture was converted into ferric oxide, probably by direct oxidation of the ferrous salt to ferric and the subsequent loss of CO_2, since ferric carbonate is unstable. In absence of moisture ferric chloride was formed.

The control of the tube-mill reaction is maintained by varying the quantities of ore, air, and moisture, the supply of chlorine being kept constant.

The roaster reactions probably are:

$$2FeCl_3 + 3MS + 3O = Fe_2O_3 + 3MCl_2 + 3S$$
$$2FeCl_3 + MS = 2FeCl_2 + MCl_2 + S$$

depending on the presence or absence of air. With excess air some of the sulphur would be burned to sulphur di-oxide. In presence of moisture some hydrochloric acid gas is formed, which at once attacks the metallic sulphides with formation of chlorides.

The refinery reactions are simple. They consist of the replacement of one metal by another.

$$MCl_2 + N = NCl_2 + M$$

The elimination of iron takes place according to the following equation:

$$2FeCl_3 + 3ZnO = Fe_2O_3 + 3ZnCl_2$$

The resultant ferric oxide is granular, quite unlike the slime produced by precipitation with ammonia.

Mechanical Problems. In handling corrosive substances like chlorine and chloride solutions, discretion has to be exercised in selecting the materials that are allowed to come in contact with them. For the tube-mill, iron is permissible, because dry chlorine even when hot does not readily attack iron. For solutions, wooden tanks are safe; and for pipe-lines, pure gum-rubber hose has a reasonable life. Valves on pipe-lines have been conveniently made by using pinchcocks on the rubber hose. Where this has not been possible for other reasons, the new alloys 'duriron' and 'tantiron' have shown great powers of resistance and have been used with satisfactory results. Pumps made from these alloys have been employed and air-lifts through wooden pipes have elsewhere demonstrated their value. Chlorine gas was handled by suction through vitribestos pipes.

Modern Blasting Practice

By P. B. McDonald

FOR blasting to best advantage, it is now recognized that the use of strong detonators makes for greater efficiency by intensifying the less sensitive explosive of the charge. The advantage of thorough tamping (or 'stemming') of drill-holes, preferably with a proper clay brought underground for the purpose, is also well understood by mine superintendents.* The recent tendencies in blasting practice have been along the line of using higher explosives, blasting longer holes and more of them at one time; and directing special attention to the primer. In general, the economy of blasting in more wholesale fashion has become apparent. Especially in stoping at mines with wide orebodies, the effort is being made to replace the small-gauge methods suitable for driving and sinking, by a system of breaking huge masses at one blast; then, if necessary, to block-hole these pieces for reduction to a size convenient for handling. Mammoth blasts, large-scale bench-stoping, and deeper drill-holes are becoming the order of the day. Of course, in narrow veins of three or four feet width, it is difficult to increase materially the proportion of the blasting; in such stopes higher explosives may solve the problem, together with more attention to the detail of primer, caps, and tamping. It is in stoping that the greatest room for improvement now lies; practice in driving and sinking is already of a high order, and the relatively self-contained and standardized procedure of advancing a drift or shaft, has been perfected to an admirable degree during late years.

Why large-scale blasting breaks more ground proportionately than scattered efforts was stated clearly by W. S. Simpson at a recent meeting of the South African Institution of Engineers, and recorded in the *Journal* of that society. Mr. Simpson says: "When two or more holes are drilled close to each other (see Fig. 1) and blasted in the usual way—that is, consecutively from below upward—these holes between them break more ground than had they been drilled far enough apart not to influence one another; there is a tendency for the holes to do their normal work—to throw out, for example, the craters *A* and *B*—and besides to throw down the rock *C* between these craters; the more nearly simultaneously the two holes are blasted, the more intermediate rock will be broken; if the holes are blasted with a long interval between blasts, little of the intermediate ground will come away."

This simple illustration indicates the gain by blasting a number of holes together, such that each hole helps the others around it. The advantage of placing long holes so that a large slab or mass of ore will be dislodged by one blast (then reducing the pieces by block holing or sledging) has effected a decided lowering of cost in the Michigan copper region, where the Calumet & Hecla, as a result of sedulous experiment, now employs 12, 14, and 16-ft. drill-holes for stoping in place of the former 6 and 8 ft. holes. The contrast in the practice of stoping, as compared to that of sinking or driving is quite definite. While the former is tending toward the use of longer holes, the latter is becoming more like the European practice of employing shorter holes and more frequent blasting. The greater flexibility of shorter 'cuts' for sinking and driving has been made possible by the introduction of the light hammer-drills both of the jack hammer and mounted types.

As Mr. Simpson's paper is not available to many American readers, a further reference to it may be of interest. He records a number of tests made in the Rand mines in order to determine the relative advantages of several explosives. The results show that in two stopes of different character, a blasting gelatine of 92.75% nitro-glycerine (and 7.25% nitro-cellulose) was 25% more efficient as an ore-breaker than a 'gelignite' of 56.4% nitro-glycerine, (with 2.5% nitro-cellulose, 30.7% sodium nitrate and 10.3% wood meal). In this he checks the manufacturer, who gave the comparative 'ballistic strength' of the two explosives at 100 and 75.6, as determined in laboratory by the ballistic pendulum method.

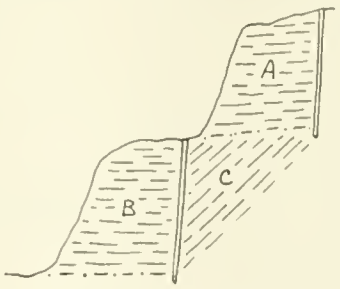

FIG. 1.

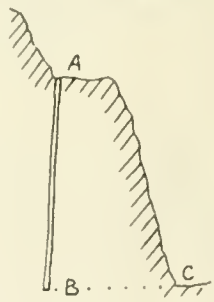

FIG. 2.

Referring to primers, Mr. Simpson has the following to say: "The primer, even if it consists of the same high grade of explosive as the charge, does not perform as much work as any one stick of the charge, because unlike them, the primer cannot be compressed to occupy the full width of the hole; however, it is not recommended to employ a cheaper explosive for a primer, though some miners advocate a primer of 40% 'ligdyn' because of its certainty and regularity of response to the detonator." The tests showed that by using 40% ligdyn as a primer for gelatines of 92.75 or 67.1% nitro-glycerine, the efficieney of the explosives was much reduced. In fact, with

*See 'The Efficiency of Tamping,' by Edgar A. Collins, M. & S. P., May 22, 1915.

the 40% primers the 92.75% gelatine broke little more ground than the 56.4% 'gelignite.' Ligdyn is a dynamite of 13% wood meal and containing, besides 40% of nitro-glycerine, 45% of sodium nitrate and 2% of wheat flour. It had been recommended previously for primers by several authorities, because, as they stated, "it increases the speed of detonation of other explosives and secures the detonation of every cartridge in the charge." In view of the seeming contradiction between the statements of Mr. Simpson and the powder experts (of whom Dr. Comey of the Du Pont company was one) as regards the efficiency of ligdyn as a primer, the following is suggested by Mr. Edward Walker of the *Mining Magazine*, "the fact that Mr. Simpson found the ligdyn primer of no assistance may be interpreted to mean that the high velocity of detonation secured by its use is not so suitable for rending hard rock (such as on the Rand) as a slower transmission of the detonating wave." This is a technical point that is now being studied by engineers and mining men.

Perhaps the most pertinent part of Mr. Simpson's paper is his discussion of burdens and sockets. The 'burden' is the width of rock between the bottoms of the hole and the face, the measurement being made at right angles to the hole. In Fig. 2 the burden is *BC*. The 'socket' is that small part of the bottom of the hole that is left after the blast; many American miners call this the 'boot.' As pointed out by Mr. Simpson, "the main factor in stoping is the adjustment of burden to depth of hole; most holes when blasted will leave a certain length of socket, say four inches; when no socket is left, the chances are that the load on the hole was too small." That is, if the hole in Fig. 2 left scarcely any socket at all it would indicate that probably a greater burden could have been employed, so that the distance *BC* could have been increased. On the other hand, had a socket of 30% of the hole been left, it would be evident that too great a burden was assumed, and the distance *BC* should be decreased. The top of a hole usually breaks easily; it is the bottom of the hole that makes the trouble. The burden, both the distance to the face and to adjoining holes, should always be measured (or estimated) as between the bottoms of the holes—not their tops.

By employing a higher explosive in stoping, a greater burden can be assumed, and the holes of a row can be spaced somewhat farther apart. A shorter socket will probably be left than with a slower explosive, and more shattering will be done, so that more rock can be picked down after the blast. Both in driving and in stoping, a higher explosive will be apt to reduce the rock fragments to smaller pieces. Some superintendents consider this an advantage, as tram-cars will hold more ore when the fragments are fine, and the coarse crushing in the rock-house or mill is simplified, as well as such inconveniences as large pieces becoming stuck in skips, chutes, and grizzlies are eliminated. However, too much attention given to reducing to fine fragments in one blast will generally result in small-scale stoping methods of higher expense than the employment of longer holes, more of them, and a generally larger scheme of blasting. An added consideration is the inevitable loss in dust of precious-metal ores when fine blasting is done. Primarily, the blasting of ore in stoping has for its object the separation of the ore from rock in place. If it breaks in huge slabs, the huger the better, for the expense of reducing these large pieces to a convenient size is insignificant as compared with the fundamental task of detaching the ore from the containing rock. Naturally a high explosive,

WHERE 'WELL-DRILLERS' ARE USED TO DRILL HOLES FOR BLASTING. THE PIT OF THE NEVADA CONSOLIDATED COPPER CO., ELY.

containing 60 or 80% nitro-glycerine, will cost more per pound than a 40% explosive. Whether the high explosive is economical in the end is a matter that must be decided for individual mines. In testing such explosives, difficulty may follow from the prejudice of the miners, who, as regards such changes, are decidedly conservative. The best method is probably that adopted by several mining companies who recently changed to the use of a higher explosive; they secured dynamite on which the proportion of nitro-glycerine was not indicated in any form, so that its higher percentage was not known to the miners, and insisted upon a prolonged trial under fair conditions.

Mr. Simpson thinks that "too often the miner is told to put more ground on his holes"; he continues, "there is in stoping a decided tendency to make the burden too large; to check this tendency, burdens and sockets should be measured frequently—the sockets measured carefully, not merely looked into—and the ratio of the socket to original length of hole determined." In considering his remarks it should be recalled that he refers to practice on the Rand, where is probably the hardest and toughest ore of any important mining region in the world, also that the lodes are comparatively narrow.

A mine-superintendent recently remarked that, disregarding the present tendency to use more powerful dynamite in smaller cartridges for the purpose of reducing the drilling, he considers that a hole drilled with smaller changes in gauge of the steel affords a tighter receptacle for the dynamite and will blast to better advantage. In other words, a more even hole (perhaps begun at 1¾ in. and ended at 1¼ in.) filled for three-quarters of its length with (1¼-in.) dynamite that fits snugly in the relatively narrow space, will ensure a better explosion, just as firm tamping improves the ordinary hole. For primers, he emphasized the desirability of an explosive fully as high as the charge. He had, he said, advocated for loading much-tapered holes a 60% dynamite in the bottom, 40% for the bulk of the charge, and a primer of 60%. The purpose of putting a higher explosive in the bottom is two: the hole is smallest there, and the burden heaviest.

Harry East Miller, formerly superintendent for the Judson Dynamite & Powder Company and the Giant Powder Co. Cons., suggests an additional reason for using the high explosive at the bottom of the hole, namely, using it as a primer. Dr. Miller maintains that the speed or velocity of detonation of the primer, and not its ballistic value, is the greater factor in the work performed by the charge. The primer he says, is but a small proportion of the charge and the extra work performed cannot be attributed to the primer itself, but to the influence that the primer exerts on the balance of the charge. Hence he recommends the use of 60% 'straight' dynamite (which is the highest grade of dynamite that can be shipped by rail) as a primer; half a cartridge is sufficient, for it is the quality and not the quantity that counts. With 'straight' dynamite the velocity of the explosive wave increases with the nitro-glycerine content but this is not the case with gelatine dynamites. This 60% dynamite will start an explosive wave of the highest order and the wave will be communicated to the remainder of the charge and make it perform the maximum work. By 'straight' dynamite is meant one that contains only nitro-glycerine and 'dope,' but no other nitro compound and no ammonium nitrate.

The American International Corporation is the name of the new combination of industrial corporations and banks, which has for its purpose the extension of American enterprise in foreign lands. It is organized under the laws of New York State with a capital of $50,000,000 and with a charter so broad as to permit the carrying on of almost any business, from gold mining on the Rand to establishing a machinery business in China, or resuscitating a coffee company in Guatemala. The chairman of the Board of Directors is Frank A. Vanderlip, the president of the National City Bank of New York, which institution is known to be an indefatigable worker for promoting American participation in foreign opportunity. Included in the large board of directors are: William E. Corey, James J. Hill, Otto H. Kahn, Ambrose Monell, John D. Ryan, and W. L. Saunders. Chase A. Stone, the president, has said, "We Americans are far behind the Europeans in building up foreign trade through association with foreign people and study of their ways. The Europeans have their young men scattered the world over. Ours have stayed at home, or, when they have ventured forth, have not had the time or the disposition for intensive study of the customs, manners, and business of foreign people." The first step taken by the new corporation was the purchase of the seven vessels of the Pacific Mail Steamship Co. operating along the west coast of North and Central America. The essential purpose of the corporation, however, is stated to be "not acquisition of property, but co-operation and resuscitation."

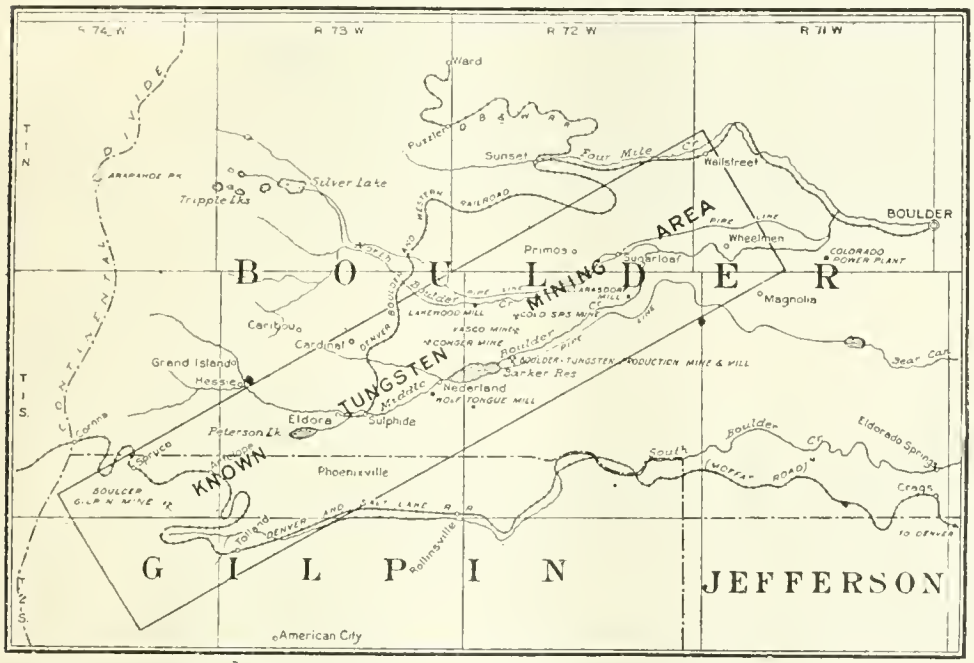
China's imports from the United States are 7.3% of the total imports into that country. Half of the imports from the United States is kerosene; the remainder includes lumber, machinery, iron and steel products, tobacco, and cotton cloth. Since the War began, American manufacturers of machinery and transportation equipment have obtained a good deal of business in China that formerly was supplied by European firms. A pamphlet recently issued by the Guaranty Trust Co. of New York predicts that "the next few years may bring among our people a greatly increased interest in China."

Large profits in zinc during the recent 'war order' times are indicated by the statement that the New Jersey Zinc Co. paid dividends in 1915, aggregating 130% on its former capital of $10,000,000; this company capitalized its large surplus through a stock dividend of 250%, which raised its capital to $35,000,000. The Butte & Superior Co. is now paying dividends at the rate of $40 per share per annum. The American Zinc Co., which has mines in eastern Tennessee that produce a high-grade spelter, declared a 50% dividend in preferred stock.

Tungsten District of Boulder County, Colorado

By Charles T. Kirk*

INTRODUCTION. Boulder county, Colorado, has been unique in having ferberite, the tungstate of iron, in commercial quantity; this explains the common saying that Boulder controls the price of tungsten. Scheelite is less desirable on account of making a pasty slag in the furnace; the higher manganese content of wolframite and hübnerite is also difficult of separation from tungsten. "It is interesting to note that two or more of the large manufacturers of incandescent lamps specify that Boulder county tungsten must be used in the filaments."[1] Only the Saxon and Bohemian deposits compare in purity with those from what was formerly called the Nederland district, but which has been so extended by recent discoveries as to become known as the Boulder County tungsten field. A recent discovery is reported only a half-mile from the town of Boulder. A convenient sketch of the 'Known Tungsten Mining Area' was published on February 20, 1916, by the *Rocky Mountain News*. This shows a belt, 4 by 20 miles, extending south-westerly from Wheelmen and Wallstreet to three miles beyond Tolland and Spruce. While the sketch is reliable, it is known that favorable country-rock exists well beyond this area, especially to the south, in Gilpin county.[2]



THE TUNGSTEN BELT OF BOULDER COUNTY, COLORADO.

A small area, 2 by 4 miles in the middle of the district, has produced two-thirds of the tungsten output. It includes the Barker, Bradley, Primos, Rogers (now Vasco), Union, and smaller tracts, the Crow patent (Colorado Tungsten Corporation) and the Boulder Tungsten Production Co., Great Northern, and other groups of claims, besides considerable Government land unclaimed. The tracts and other areas patented before being taken as tungsten mining land have vertical side-lines, but the mining claims located as such are under the law of the apex.

The only comprehensive publication concerning this area[3] is now exhausted, while a reprint is soon to appear, the following notes will doubtless have a wider circulation than the necessarily limited State paper. As I have made detailed examinations of only special portions of the field, I have secured permission to add to my observations from other sources, as cited. I have to thank Dr. R. D. George, as well as Messrs. Fair, Clark, and Rafter for many courtesies.

ACCESSIBILITY. The middle of the district lies 15 miles south-west of Boulder, or 45 miles north-west of Denver. It is reached by the Denver, Northwestern & Pacific Railway to Rollinsville, near its southern border, and by the Colorado & Northwestern (an extension of the Colorado & Southern) to Cardinal, near its western border, 2 miles west of Nederland. The latter line is to connect with Nederland this summer. Interurban trains run on the Colorado & Southern tracks between Denver and Boulder, and from the latter place connect with Nederland, 20 miles distant, by an excellent county automobile road up Middle Boulder canyon. This last is by far the most rapid route, making Nederland only three hours from Denver.

PHYSICAL FEATURES. The relief of the region is rugged, ranging from under 7000 to over 9000 ft. Sugarloaf and Bald mountains and others are evidence of even a higher level that has been reduced by erosion.

*Engineering geologist, Albuquerque, New Mexico.

[2]George, p. 85, and recently reported discoveries.

[3]"The Main Tungsten Area of Boulder county, Colorado," by R D. George, State Geologist, with notes on the intrusive rocks by R. D. Crawford, geologist; First Rept. Colo. Geol. Survey, State University, Boulder, Colorado.

As this chain is a part of the Front Range, the influence of the plains causes the snow to disappear earlier than in the more remote mountain regions. Only 20 inches of precipitation is recorded annually. The country is therefore sparsely wooded, but good spruce and pine saw timber abounds locally, while smaller growth is well distributed.

Fuel and Power. The local supply of wood is much used for fuel, but the plentiful coal resources of Colorado can be drawn upon at moderate expense for fuel and power. Abundant electric power is developed from the reservoir of the Colorado Power Co. in the Boulder Creek valley near the middle of the district. This creek below the dam runs 15 to 20 second-feet, which is a plentiful supply for ordinary mining purposes.

Country-Rock. The region is part of a typical pre-Cambrian complex of probably sedimentary[4] gneiss, with local schist, intruded in irregular fashion by normal biotite granite. Dikes of pegmatite and of fine-grained granite have followed the solidification of the earlier magmas, while a series of basic dikes—not fully correlated mutually, but apparently ranging from acid to basic in order of age—intruded after the pegmatite and before the tungsten metallization. A dike of fine-grained granite trends roughly parallel with a belt of productive mines in the north-eastern part of the district, while hornblende-andesite dikes trend nearly east-west through the productive area about Nederland. Within the massive granite I observed many rock inclusions, remote from contacts, some of them apparently of schistose structure but others decidedly not. None was longer than 15 inches, but much larger blocks have been noticed near contacts.[5] Some of the smaller xenoliths are well rounded, while others are sub-angular to sharp. Tongues of fine-grained granite intruding into the metamorphics, as well as much baking of the gneiss and schist, are significant features of the contacts.

The Veins. These are the latest structural features. They are generally well defined, and vary from less than an inch to as much as 14 ft. in width,[6] running commonly 2 to 4 ft. Where they pass through granite country, the foot-wall is frequently gneissoid. The tungsten-bearing portion of the vein may lie either on the foot or hanging wall, or it may ramble from side to side. It may range from $\frac{1}{8}$ to 15 inches of solid ferberite, but where thicker it usually branches into small stringers. Almost no replacement of the wall-rock is noticeable, and delicate qualitative tests made upon a well-fluxed and thoroughly digested sample of wall-rock taken but two inches from a 2-inch ferberite vein showed only a trace of tungsten.

The persistence of the veins, both in width and metallization, is more dependable along the dip than strike, as shown in the workings of the Conger, Rafter, and Barker mines. The veins sometimes coincide with the laminations of the gneiss, where that rock encases them, but evidently are not generally so controlled. Possibly they are most associated in direction with the pegmatite dikes, and therefore appear to be re-openings along these old planes of weakness. An examination of the vein matter shows that it has been brecciated at least three times, and though the extent of the movements cannot be determined, they appear to have been only a few feet. While the veins occasionally strike north-west, in the main they range into the north-easterly quadrant. In this respect, as well as in some others,[7] they seem related to the gold-bearing veins of Gilpin county, directly south-west of the tungsten district. Most of the tungsten veins of north-easterly strike have a steep dip to north-west usually from 75 to 90°. Vein intersections are common, though but little offsetting can be detected at the crossings. Almost invariably the intersections favor good ore-shoots, with occasionally such bonanzas as the Conger, the Barker No. 3, and the Parker-Elmette vein-junction in the Rafter group.

In the mines along the deeper creeks the water-level may be 500 ft. from the surface. In the Barker No. 3 shaft, almost on the bank of the reservoir, only 400 gallons per day was drawn from the 225-ft. level. It is interesting to note that a drift on the 140-ft. level, extending under the reservoir to within 50 ft. of its bottom, was nearly dry. In areas of less relief, the water-level is from 200 to 100 ft. below the surface.

The vein-filling consists commonly of brecciated granite, gneiss, pegmatite, or occasional schist, all somewhat kaolinized and stained by iron oxides in the present workings. Into these rock-filled fissures, and into many others not so filled, there have been introduced no less than four successive solutions containing silica and tungsten. The silica is usually crystalline, but is occasionally of the chalcedonic type, known locally as bone and hornstone. Possibly more of this hornstone was found in the earlier workings in the eastern part of the district,[8] but it shows in some of the present mines at depth.

The ferberite occurs in three distinct types: (1) well-defined crusts, vugs, and open breccias, including a cemented breccia of the 'peanut-ore' type; (2) massive and firm fillings, not generally associated with breccia; (3) highly silicious ore, sometimes crystalline, but usually sub-crystalline (hornstone) and often frozen to the ferberite.

Among the occasional minor minerals in the ore are hübnerite (manganese tungstate), scheelite (calcium tungstate), and wolframite (iron-manganese tungstate). In earlier reports wolframite is discussed in connection with these deposits, but this mineral has been shown, by Hess and Schaller, to be ferberite.[9] These writers assert that the manganese content of the tungstate increases from south to north across the district.

Among the uncommon minerals not bearing tungsten, the sulphides sphalerite, galena, chalcopyrite, and molybdenite have been noticed, as have also the oxides

magnetite, hematite, and limonite. Much of the magnetite contains manganese, and occurs in small massive lumps easily mistaken for ferberite, especially in surface exposures with crystalline quartz. In the north-east, near Wheelmen, a telluride of gold and silver, probably sylvanite, is not uncommon. Gold in some form is present in nearly all the tungsten ores, in places in commercial quantity; indeed, many of the dumps and stope-fillings of former gold mines are now being re-treated at great profit for tungsten. Fluorite is doubtfully accounted, and both adularia and valencianite (secondary forms of orthoclase) are reported.[10] While sericite (secondary muscovite) has not been revealed by the microscope, other conditions of mineralization and the general appearance of the wall-rock suggest its presence. The weathered granite, which I examined with only a lens, did not reveal evidence of propylitic action[11] other than the reasonably sure presence of sericite and the fine-grained silica. The absence of cassiterite, tourmaline, and other common associates of tungsten is remarkable.

[10]Lindgren, *Econ. Geol.* Vol. 2, pp. 461-463, 1907.

[11]Kirk, *Econ. Geol.* Vol. 7, p. 67, January 1912.

Probable Conditions of Mineralization. Hess and Schaller state[12]:

"It seems probable that the tungsten minerals may have been deposited from the latter water emanating from magmas, and silver and gold from the solutions after they have somewhat cooled." This conclusion would provoke the inference that the Gilpin county gold deposits are of a higher level, the extension of which has been eroded. Spurr, Ball,[13] and Ransome[14] bear out Lindgren's conclusion that as much as 5000 ft. of rock has disappeared from the tungsten area. In the discussion cited, Lindgren uses the conclusions of Spurr, Ransome, and Ball together with his own inferences based upon the significant mineral associations mentioned above, and classifies these deposits among those of intermediate vein-zone depths—4000 to 12,000 ft. below the surface at the time of their filling.

A small amount of characteristic alteration (propylitization) is apparent, as well as evidence of too much brecciation and open vein-filling for the lower depth given for that zone. On the whole, the evidence seems to permit the supposition that the deposits as explored at present—to 1000 ft. in depth—were formed near the top of Lindgren's intermediate vein-zone, or at about 6000 ft. from what was then the surface.

Origin of the Ore. Reasonably good evidence in the form of inclusions of different kinds of rocks, some of them well rounded, evidently by digestion and absorption into the granitic magma, indicates that there was a variegated roof-rock over this magma; indeed, it seems probable from certain erosion remnants that several thousand feet of rock has been removed since the cooling of the granite. It is also known that ferberite is slightly soluble in ordinary vadose (meteoric or surface) waters. This seems the strongest tangible evidence at hand to account for deposition by downward enrichment from formerly overlying rocks of possible tungsten content.

Opposed to these threads of evidence are (1) the fact that they do not suggest a source for the metal; (2) the tungsten minerals have close genetic association with a typical acid magma; (3) they have genetic connection also with the post-Cretaceous formation of the Front range, that time being one of widespread metallization throughout the Rocky Mountain region; (4) the evidence cited from Lindgren and others indicates that the ore was deposited at intermediate depths, probably 6000 ft., rather deep for the effective downward circulation of meteoric waters; (5) there is an absence of sources for acids stronger than humous or carbonic types, there being almost no sulphides in these deposits; (6) the tungsten minerals are only slightly soluble in the carbonic and other acids to be found in water near surface, no downward enrichment being recognizable in the existing mine workings; (7) the veins are constant in depth as far as developed, about 1000 ft., being more dependable in this direction than is usually the case horizontally.

These and other observations appear to show that the metals emanated from the granitic magma below, probably long after the solidification of at least the upper zone. The many generations of thermal vein-minerals signify that the cooling and contraction causing the earthquake action that shattered and sheared the veins extended over a long period, and that emanations of silica and ferberite-forming constituents continued till the sources below were cut off through solidification.

Depth of the Orebodies. Upon the source and manner of deposition of the ore depends largely the life of the tungsten mines. The conclusion that the metallization occurred from below upward seems well justified, and the continuity of the veins to much greater depth than yet prospected is reasonably assured. I have made close studies of the veins at Butte; those, though metallized chiefly in copper, are similar to the veins of Boulder county in several respects. From the tightness and intense propylitization of the Butte veins, as compared with the Boulder veins, it would appear that the parts left by erosion at Butte were formed much deeper than the tungsten deposits as mined at present. It seems fair to infer, then, that the latter may persist to even greater depth than the present lowest levels of the Butte mines—3000 feet.

Hints on Prospecting. The following points on prospecting are classified into unfavorable and favorable conditions. Among the first are:

(1) Schistose areas and those of more easily crushed gneiss do not generally carry continuous veins.

(2) Areas where chalcedony is abundant generally yield ore difficult to concentration, especially in depth.

(3) Time may be wasted by sinking on a showing of manganese-bearing magnetite that resembles ferberite. A weak magnet will attract this mineral, while a powerful magnet will be needed to pick up the ferberite. The streak of magnetite is black while that of ferberite is brownish black to reddish black—becoming more ruddy where exposed to weathering. Hematite has a dull-red streak, and is lighter in weight and harder than ferberite. Hübnerite, the manganese tungstate, less desirable than ferberite, is rare. Its elongated, hair-brown crystals are easily distinguished from the rhombic glossy black crystals of ferberite.

The more favorable conditions are:

1. Areas in the neighborhood of pegmatite veins.

2. Many prospectors and engineers have faith in the country near the basic dikes, especially those of hornblende-andesite and pyroxene-andesite.

3. Occasionally a fault-zone along or across a hill is denoted by a valley. But valleys are also eroded in the schist belts, so that this is only a suggestion.

4. Ferberite withstands weathering, and may therefore be found naturally exposed, especially on steep slopes, in dikes of pegmatite, and in float broken from either of these.

5. Where conditions are favorable, it is sometimes

[12] U. S. Geol. Survey Bull. 583, p. 14, 1914.

[13] U. S. Geological Survey, Prof. Paper 63, p. 145, 1908.

[14] U. S. Geological Survey Prof. Paper 75, pp. 60-62, 1911.

advantageous to undercut the vein by an adit; but since the ore is generally more persistent in dip than in strike, it is well to prove the vein by sinking at or near the point of discovery.

6. Assays are not generally necessary. Ferberite is easily distinguished from other minerals occurring in these deposits by its high specific gravity (7.5), and its bright, almost cubic crystals of easy cleavage and dull reddish-brown streak (or fine powder). The prospector soon learns that it is folly to discard any ferberite at all. When tungstic acid is worth $100 per unit ($5 per pound) pure ferberite is worth about $4 per pound. It is well to have assays made of old dumps, for in these the ferberite may be ground or weathered too fine for recognition.

Leasing. A large part of the production comes from lessees, who pay a 25% royalty and operate under agreements subject to cancellation on 90 days' notice. Occasionally the lessee contracts to mine at the same royalty a block of ground of, say, 70 by 100 ft. within the vein, and may proceed until it is all extracted, provided he does so continuously—day by day. Some operators have engaged to lease a definite distance along any veins cut in an adit for a period of two years from the time the veins are cut, provided they work continuously. The method of development by leasing is satisfactory to the lessee, who in turn exploits the ore possibilities in that part of the vein near his lease, and also gives a fair cash return for his rights.

Milling. Some of the ore does not need concentration, but much of it must be milled to bring it up to 60 or even 48% grade. None of it is refined to tungstic acid on the ground. A small penalty is exacted for shipments running below 60% WO_3; ore running above 0.25% phosphorus or 0.01% sulphur is not sold. The ferberite is ordinarily more easily crushed than its gangues, so that careful dressing is necessary. R. D. George, State geologist of Colorado, has shown by experiment that stamping the ore till it is separated from the gangue reduces it to a pulp that will remain long in suspension, causing large losses in the tailing. As a result recent mills have installed initial grizzlies, followed by coarse jaw-crushing of oversize and immediate screening, passing thence to rolls for finer sizing and screening, lessening the possibility of 'pulping' to a small portion of the ore. This dressing is seen to be not unlike that applied to the zinc ores of Missouri.

Silver is used for a nation's coinage whenever a large amount of small coins is needed, as in paying troops, even though the gold standard is the basis of exchange in the country. When prolonged uncertainties of war or financial straits cause the hoarding of gold, a demand for silver coin ensues. In a recent discussion of silver for coinage, the *New York Times* asks the following question and answers it: "Why should a Government go to the trouble and expense of buying silver for coinage? Why not go on issuing paper money for circulation? Is not the fact that a Government is able to buy silver proof enough of its solvency? The answer is that money must be related to people. Theory alone will not suffice. Traditions, habits, and prejudices have to be considered. There is a limit to the amount of paper money that people will freely accept. The limit is variable between different people. It is probably much lower in Russia than in France and England. But with any people there is a more or less definite ratio which metal money should bear to paper money. Paper money has been increased enormously in Europe. That circumstance alone would call for a greater coinage of silver. But it is probable that at the same time people have been hoarding silver. That would be only natural. Gold they are forbidden to hoard; silver they may. If they save at all, they would be at liberty to put silver aside and spend the paper money. Silver has an intrinsic value and always will have. Paper money, no matter how much confidence you have in it, is open to risk. Silver in hand would not be changed in value by the outcome of war, whereas some of the paper money now appearing in Europe may be greatly depreciated by the conditions of peace."

Tempering Drill-Steel

One of the companies that manufactures rock-drills recommends, for the tempering of drill-steel, the use of a special solution of blue vitriol and sal-ammoniac in place of water. Such a solution, as used at the testing-plant of the company, is mixed in an earthen jar in the ratio of 7 lb. of blue vitriol and 4 lb. of sal-ammoniac to 15 gallons of soft or distilled water. It is necessary, with this solution, to provide a hood just overhead with stove-pipe attached, to conduct the fume that arises when the bits are tempered. In case it is not practical to use this special tempering-bath, a strong brine is recommended. Although not absolutely necessary, it is preferable to anneal the steel after forging it and before tempering: this is best done by heating the steel a trifle higher than the tempering-heat and laying it across a piece of iron or in dry ashes to cool to blackness; care should be exercised not to place the steel on the damp ground to cool, as this rapidly conducts the heat away and produces strains in the steel.

To temper, heat the bit slowly to a bright cherry-red for about three inches from the cutting-face, and plunge in the bath for $\frac{1}{2}$ or $\frac{3}{4}$ in., holding the steel vertical and moving it slightly until the cutting-edges are cool. Then plunge the entire bit for 6 or 8 in. into the bath and withdraw quickly, after which one wing should be polished in order to detect the proper tempering color. When this color is secured at the bit end, quench it in oil, letting it remain there until cold.

A quicker method of tempering is to anneal the steel, bank the fire, and insert the bit, heating only $\frac{1}{4}$ to $\frac{3}{8}$ in. When the desired heat is obtained—a cherry-red—the bit is simply plunged and left in the brine to cool. The manufacturing company, which recommends the above methods, advises "not to use clear water for tempering, as the acid solution or brine gives much better results."

Concentration of Quicksilver Ores

As previously announced by the State Mineralogist, Fletcher Hamilton, an investigation is being conducted into the methods of concentration of quicksilver ores. The experimental work is being carried on in the mill of the Department of Mining, at the University of California, Berkeley, by Walter W. Bradley, of the staff of the State Mining Bureau. Much experimental work has yet to be done, but sufficient data have been gained, so far, to make a preliminary statement of partial results, pending the issuance of the final report in bulletin form later. This is done in the hope that it may assist those who are making inquiries along these lines, and also that it may elicit suggestions from those who are similarly experimenting at various mines throughout the State.

Aside from the present war-begotten flurry of high prices, quicksilver mining in California has become more and more a question of economically handling larger tonnages of lower grade ores. Since Robert Scott evolved his fine-ore, tile furnace in 1871, there have been no improvements worthy of mention in the metallurgy of quicksilver until the present agitation for concentrating. A very surprising feature of the situation, particularly to one familiar with metallurgical practices in the reduction of gold, silver, copper, etc., is the absolute lack of any systematic sampling and assaying at the quicksilver mines. So far as we have observed there is not a quicksilver mine in California which possesses or utilizes an assay-office, at least there was none up to within the last six months. The distillation assay with the Whitten apparatus is simple, quick, and accurate. The old-timers have been complacently saying "the furnace gets it all," and that therefore they did not need to assay. It is doubtful if the Scott fine-ore furnaces in operation in California are averaging 75% extraction. In addition they are notorious for the quicksilver absorbed by the furnace and condenser walls; also soot is formed which has to be re-treated for contained mercury. The products of fuel combustion being mixed with the vaporized mercury, cause condensing troubles.

Our experiments have shown that high extraction (above 90%) can be obtained by water concentration on tables, with friable ores in which the cinnabar is distinctly crystalline. Crushing by rolls produces a minimum of slime. If, however, the pulp contains a cinnabar slime, either from 'paint' ores, or by reason of having to crush fine to release the sulphide, the extraction by tables will be low. In such cases, though, it can be improved by classification, and treating the different sizes on separate tables. The slimed cinnabar can be recovered by flotation. A high extraction has been obtained by flotation tests in finely-ground (−80 mesh) fresh ores, utilizing either pine-oil derivatives or eucalyptus oils. We say "fresh" ores, because, contrary to common conception, cinnabar on exposure does oxidize sufficiently to affect flotation results, as some of our tests have indicated. Good results were obtained by table concentration on an ore carrying natural quicksilver.

The concentrates being obtained, have yet to be roasted. Retorts are of limited capacity; and the concentrate, because of its high specific gravity, requires stirring to prevent packing. A small furnace of the Scott type could be used, with a narrower shaft and narrow shelf slit; such as in use at the New Idria mine for treating soot. Here again we have the fuel-combustion products mixed with the quicksilver vapor, and the attendant condensing difficulties. Some form of rotary roaster may be adapted, or a small-size unit of the McDougall or Wedge type of mechanically rabbled furnace muffle-fired.

The ultimate decision between a straight furnace-reduction or concentration and roasting of the concentrate, will be a matter of comparative cost coupled with comparative extraction. The initial installation of a Scott fine-ore furnace unit is high (including condensers, etc., $1000 per ton-day capacity. We know of instances where the cost has been materially less than this figure, but they are the exception rather than the rule); the extraction is low (in the majority of cases probably less than 75%); cost of operation is low (50c. to 75c. per ton for large units, economically managed, though this does not include high cost-repair, interest, or depreciation on the high initial installation capital). A concentrating plant of equal capacity will require less than one-tenth the initial capital expenditure, and a correspondingly lower depreciation charge; it will give 25 to 30% higher extraction; but the operating cost, on account of finer crushing, will be 30 to 50% higher. These points will have to be determined for each individual property.

Gold as a factor in finance was discussed by Mr. Adam Shortt at a recent meeting of the Canadian Mining Institute. "Gold," he stated, "is used in international exchange only to meet the temporary fluctuations in point of limited time. Owing to the fact that London has been the exchange centre of the world, and that people everywhere have confidence in the soundness of its finances, many of the sales effected between distant countries, for instance, between South America and China and Japan, pass through London, although the goods may not go within two or three thousand miles of England." This is not due so much to the accumulation of an enormous gold reserve, as France can probably furnish more gold than Great Britain. But it is a consequence of the great foreign trade and inter-relations of Britain. "The actual test of the efficiency of the credit of a nation is the small amount of gold that is required to serve and maintain that credit." This last pronouncement has a direct bearing upon the investigation being made in Canada as to the advisability of increasing the Dominion's gold reserve. Likewise it relates to a condition of finance in this country, where the amount of gold maintained has never been large, until recent importations in consequence of 'war orders' have diverted a good deal of gold from Europe to the United States.

GENERAL VIEW OF ATOLIA FROM THE RAILROAD STATION.

The Tungsten Mines of Atolia

By Charles T. Hutchinson

ATOLIA is near the boundary between San Bernardino and Kern counties, California, about 40 miles west of Kramer, a station on the Santa Fe railroad. This detailed statement is rendered necessary by the fact that until about a year ago nobody would have cared where Atolia was. Now thousands of people, at war and at peace, are directly affected by the well-being of Atolia, or, to be more specific, the Atolia Mining Company, which is the nucleus around which Atolia has grown.

The reason for this is the output of tungsten ore, of which the Atolia Mining Company is one of the largest producers in the United States. A comparatively short time ago, the output from the scheelite deposits of the Mohave desert was of no importance. The bulk of the tungsten used in the United States was imported from Europe; the prevailing price at that time, about $7.50 per unit in the spring of 1914, was such that with careful management a small profit could be made by operating the company's mines and mill, and in treating small quantities of ore mined by lessees and owners of small mines near-by.

Now, however, tungsten has become one of the lustiest of all 'war babies,' and the Atolia Mining Company has jumped from comparative obscurity into such prominence that when a fire partly destroyed the mill in January last, the market price of tungsten immediately jumped from $35 per unit to $75 and over, but which is now somewhat lower.

When the Allies began to organize their munition department in real earnest, orders for millions upon millions in various iron and steel products were placed in the United States. To machine this iron and steel, correspondingly great quantities of high-speed steel for cutting-tools were required, while the great machine-shops of Europe were equally clamorous in their demand. Tungsten is the alloy commonly used in making steel of this character, most of the high-speed tool-steel carrying from 12 to 18% of tungsten. A price of 65c. before the War has jumped to over $3.25 per pound at present writing, and the supply is inadequate to fill the demand. It has even been stated that one of the great American steel companies had an order from Europe for 26,000,000 lb. of high-speed tool-steel at a price of about $3 per pound. It is not surprising, then, that the well-informed are curious about Atolia.

The method of milling the ore is comparatively simple, wet concentration being used. Primary breaking is done in a Hercules-Blake crusher, while the finer grinding is completed in a Marcy ball-mill and Huntington under-driven roller-mills. Sand and slime are separated by Dorr duplex classifiers, while Callow tanks are used for dewatering; subsequent concentration is effected by Deister Simplex double and single-deck tables. The concentrate is then sacked in the usual way, while the tailing is dewatered in an Oliver continuous filter and the cake carried to the tailing-pile by a trough-belt conveyor. The slime-tailing is deposited in a separate settling-pond where it is impounded for ultimate re-treatment. Hand-jigs fill a useful function in eliminating much of the slime before concentration.

Preparations were under way at the mill to substitute electric motors throughout, in place of distillate-engines; in fact, only one of the distillate-engines was in commission at the time of the fire, and it was this engine that was responsible for the conflagration. Back-firing caused the almost complete destruction of the mill, followed by an increase in the price of tungsten of $45 per unit, and of high-speed tool-steel $2.75 per pound.

Atolia is teeming with life. Even beyond the city's limits, if there be such, the subtle influence of the boom is felt. On the way in the train, the conductor whispered mysteriously of great deposits of the once base, now nearly precious, metal. Taking an automobile as a

substitute for the slow train from Kramer, and voyaging recklessly toward Atolia over the thank-you-ma'ams masquerading as a road, the chauffeur gently insinuated that he knew of a fine deposit of "placer tungsten," which could be made to "pay big" for an expenditure of only $1500.

Estimates from various sources place the present population at 850 souls, and some Mexicans. The appearance of the tented city is pleasantly reminiscent of Tonopah and Goldfield during the early days. The mines and mill of the Atolia company are operated on three 8-hour shifts; the same is true of the construction crew at work on the re-building of the mill. The restaurants meet the exigencies imposed by these conditions and are on the job all the time. Accommodations for strangers, and even old-time residents of, say, a week's standing, are nil. Space there is plenty, tents are scarce, hotels are non-existent. One miner rather pathetically observed through the wicket-window at the company's office that he had been "on the pay-roll four days," that he had been "sleeping on the soft side of a pile of lumber for four nights," and that resulting therefrom had come upon him "the gol-durndest kink in his back that ever was," and that therefore an enforced rest was necessitated until such time as a bed and tent could be procured for him by fair means or foul.

The chief of construction, finding certain topographic advantages in that portion of the city corresponding to Forty-second and Broadway, pre-empted the greater portion of it for use as a framing-yard, and three shifts of millwrights are busily engaged in framing the new building. It is an almost continuous procession of building material, machinery, and supplies that passes from the railroad freight-platform down the street to the mill. Record time was made in the work of rehabilitation after the fire. The still-smoking ruins were removed in a few days, such machinery as presented possibilities of repairs was hauled out of the débris and new parts ordered, while the scrap was piled up to one side. As fast as new machinery arrived on the ground it was installed and put to work, and the production of concentrate was well under way long before there was even a suggestion of a roof over the building. Weather conditions fortunately were favorable, while the management of the mine was not of the type that is dismayed by obstacles. Tungsten at $60 per unit and fairly strong is a powerful spur toward strenuous efforts at renewed production.

The camp has no water, so from four to five carloads, each of 10,000 gallons, have to be freighted daily from Kramer, a distance of about 40 miles. The cost per carload is $18.50. This quantity represents the total consumption of both mill and town; the company furnishes the domestic water-supply, having installed tank-storage and an electrically-driven pump for the purpose. In order to save the enormous waste of water ordinarily incident to wet concentration, an Oliver filter was purchased, for dewatering all the tailing.

The scarcity and high cost of water would indicate that Atolia is a dry town. As a matter of fact it is, literally, being geographically within the confines of San Bernardino county, which has been 'on the wagon' for some years. Randsburg is the nearest dispensary of the kind of wet goods that comes in bottles and kegs, but, strange to say, there is little visual evidence of over indulgence on the part of the people of Atolia—in fact, of any indulgence at all. A place on the pay-roll is contingent upon regularity of attendance and performance of duties; wages are good and the 8-hour day prevails; so it would appear that the American workman is beginning to realize that 40-rod whiskey and all-night sprees are not the Gold Dust twins that produce either happiness or prosperity. An imposing dignitary, slouch hatted and starred, stalks around the camp all day in his capacity of representative of the majesty of the law, and if it were not for the high-grader, his position would be a sinecure indeed.

The high-grader, like the poor, seems always with us. Now that the value of tungsten ores may be expressed in terms of pounds, rather than tons, the temptation is great for the mentally weak to walk off with their shirt-fronts bulging with rich specimen rock. One man was caught red-handed with no less than 180 pounds of high-grade in a sack on his back. A trip at the county expense to Barstow was the result, and the offender will have a few years before him in which to realize that honesty pays.

The names of the adjoining towns would indicate that the original discoverers had spent some time in South Africa. Thus we have Johannesburg, Randsburg, and Rand, all within about ten miles of Atolia. Many of those employed by the Atolia company 'commute' between Atolia, Randsburg, and Johannesburg, by aid of the omnipresent jitney, the handiwork of the great pacifist of Detroit being everywhere in evidence. Round-trip tickets between Johannesburg, or Jo'burg in the vernacular of the native, cost 50 cents. There is a good desert hotel at Johannesburg, for some reason named neither the Palace nor the Grand. It is operated on the Golden Rule plan, by which guests are informed as to rates and then let blissfully alone until ready to depart. Each guest renders a verbal account of his meals and sleeps, pays his bill, and departs. This is no place for the certified public accountant.

The hospitality of the waste places is proverbial, the honesty likewise, and, take it all in all, there is a fascination about the desert peculiarly its own. One morning, three old-timers were sitting outside my bedroom-window, comparing notes on the topics of the day. The conversation switched to the comparative merits of the various intellectual centres of the Mohave desert. After listening to the views of his companions, one old patriarch said, with an air of finality that left no room for doubt, "I have tramped this desert for nigh onto forty years; I bin to Ballarat, Lone Pine, Barstow, and once I was way over to Bakersfield. I bin everywhere in this whole country, and take it all in all, little old Jo'burg is good enough for me."

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

Ore Production.—Mining Law.—Silver, Iron, and Manganese Ores.

Leadville's output is growing at a great rate. During April, approximately 72,500 tons of ore was sent out, an increase of 10,000 tons over the quantity in February. The greater part of the ore is zinc carbonate and zinc-lead sulphide, products which have been rushed onto the market because of the prevailing high prices. The Western Mining Co., shipping 350 tons of carbonate daily, led the individual producers with a total output of 10,500 tons for the month. The Ibex, Garbutt, Yak, Iron Silver, and Star, each produced from 200 to 350 tons per day. The Star dispatched 350 tons of manganese ore. New properties are commencing continually and the district's production is growing accordingly. It is estimated that the output for the year will total over $18,000,000.

The proposed Federal mining law now pending in Congress is not thorough enough; this is the conclusion arrived at by the Lake County Metal Miner's Association at a meeting held recently for the purpose of considering the measure. The new law would not be complete and would not offer provisions that would entirely remedy the defects of the present statute, and therefore, could not be considered as a desirable change. Additional litigation and court rulings would be required to make the proposed law workable. Copies of the report of the committee on the mining law signed by R. D. McLeod (city attorney), and W. O. Reynolds, Harry Mamlock, H. H. Norton, and John Harvey, well-known mining men, will be mailed to Bulkley Wells, chairman of the Colorado Metal Miner's Association. Other copies will be forwarded to Senator Charles S. Thomas and Congressman Edward T. Taylor, both of Colorado and chairmen of the mining committees in Congress. Among the faults found in the present mining laws, and which are not fully provided for in the pending measure are the apex theory, the procedure of acquiring rights to claims where mineral is not near the surface and where discovery must be long deferred, tunnel locations and the complications arising from them, the law of discovery, the law of assessment, individnal privilege for the location of unlimited number of claims, and locations by proxy. Some alteration has been made in the new law which is regarded as an improvement over the existing measure in connection with the above shortcomings, but the improvement is not as great as the mining industry has the right to hope for and expect. Should the proposed measure be adopted in its present form, it will prevent the introduction of a better bill in Congress for a long period, and would cause a new and troublesome era of litigation over new phraseology that has been snbstituted for language already construed by the Courts. In short, the mining bill does not provide proper legal authority for the requirements of the mining industry. It should be killed in Congress and an ample provision drawn-up without further delay.

Leadville is a heavy producer of silver ore, and the recent advance in price is of importance here. Such properties as the Louisville, Dinero, Yak, and New Monarch secure the greater part of their revenue from the silver in their ores. Every mine in this district, with the possible exception of the zinc properties, produces some silver, and the increased value of the metal will make a material difference in the settlements. In the Dinero and Louisville, ore is mined that contains as much as 5000 oz. of silver per ton. Iron properties are also reaping the benefit of the high price of silver. In the past it has been difficult to operate these mines, mainly as there was little received for the silver. All the iron produced in the district contains from 3 to 15 oz. silver per ton, and the price offered for the ore has been just sufficient to pay for mining it. Iron operators now are able to develop their properties at a fair profit, with the result that a number of old abandoned iron mines are being re-opened.

The Julia Mining Co., incorporated, with a capital of $10,000, has purchased the Cloud City and Home Extension properties in the Down Town mining area now being drained through the Penrose shaft. A few men are employed at the Home Extension installing machinery and repairing the shaft, which is 600 ft. Large bodies of iron and manganese are known to exist in the property; these will be re-opened as soon as the shaft work is completed. The Cloud City and Home Extension have been idle since 1907. At that time they were heavy producers of these ores. Trouble in coping with the water and low prices for ore closed the properties. The resumption of activity is partly due to the draining of the ground through the Penrose, but more so to the high prices offered for manganese. The Extension is expected to commence shipping in the next few weeks. Clarence Jarbeau, a retired Denver attorney and well-known Colorado mining man, is the organizer and manager of the new company. Associated with him are Mayer Harrison of Denver and Edwin R. Cooper of Los Angeles.

A well-known Leadville man, W. J. Davis, has organized a local leasing company for the purpose of developing the North Side claims on north Fryer hill. A new shaft is being sunk about a quarter of a mile south-west of the Harvard where the U. S. S. R. & E. Co. is draining the entire section. The territory is rich in iron, manganese, and lead-silver ores.

Cramer & Co., operating the Star No. 5, Waterloo, Yankee Doodle, and Aetna properties on Carbonate hill, have opened the largest bodies of iron-manganese ever encountered in the district. Contracts for the ore have been closed with the Colorado Fuel & Iron Co. at Pueblo, and a steady output of 200 tons per day is made. The properties are also prodncing a good deal of carbonate of zinc and flnxing iron. With the exception of the Star No. 5, these properties have been closed down for a number of years, and it is only the recent demand for manganese and iron that has brought them back to activity. The Porter shaft on the Star property is also shipping 100 tons daily of manganese ore, this going to the C. F. & I. at Pueblo.

WASHINGTON, D. C.

Leasing Bill, Oil Reserves, Mining Law

After a delay of several weeks, Senator Phelan of California has written his report to the Senate on the so-called leasing bill for the exploration of oil, gas, etc. It has been ordered out favorably by the Committee on public lands, being a substitute for the Ferris bill passed by the House of Representatives. The Senate's amended bill differs in the main from that of the House through its omission of the section bearing on coal lands in the public domain. It is stated that a separate bill covering the disposition of this point will be presented later

and urged for passage. The omission is a considerable surprise, and it is considered at Washington that it was decided on to help along the passage of the bill, as it has been reported to the Senate by the elimination of the opposition of the coal men, leaving these to fight their battle separately later and weaker thereby. However the coal men are fighting more than anything else the principle involved in the leasing idea, and they can combat it as successfully as if it included in its scope coal leasing as well.

The naval oil reserves are also discussed in the Phelan report. It seems to question the good to the Government in burning oil on its ships with the valuable by-products unextracted, and it asks if the Government is not going to perpetrate such waste is it going into the business of refining? The report declares that "the navy should not lay its hands on the legitimate business of the man who located and developed the oil in limited areas, and revealed the wealth of the West to a country now conscious of its greatness." Congress should grant equitable relief to such claimants, the report asserts.

It is however not likely that the bill will receive any immediate consideration in the Senate, especially if it is going to evoke discussion, as it surely will, because the calendar is being crowded with other highly important business, while the summer is coming on fast and Congress wishes to adjourn as early as possible.

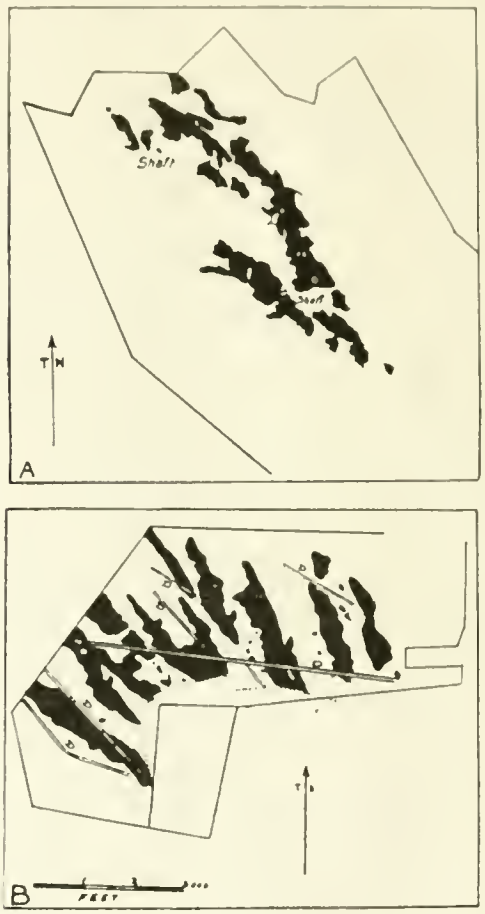
The measures in Congress calling for the codification and revision of the mining laws are dormant. The House Committee on mines and mining has done nothing so far with reference to the Foster bill, making the codification. The special sub-committee appointed to study and draft the final proposition has not met once. In the meantime the Committee is receiving a number of communications from mining men and lawyers all over the country in criticism (some of it most caustic) and elucidation of the Foster measure, which has been declared wholly tentative.

JOHANNESBURG, TRANSVAAL

American Capital for the Rand.—Underground Conditions.

According to a cable from London an American syndicate has been formed to help exploit the Far East Rand. W. W. Mein and Karl Hoffman, both well-known figures on the Rand, are named as the engineers of this syndicate. I had no notion that anything was on the carpet when I wrote my last notes. The syndicate has every chance of doing well, and the promoters are to be congratulated on engaging engineers who have had former Rand experience. An idea that mining on the Rand is a simple stereotyped business, and requires only capable 'muck-shifters,' is one of those fallacies that die hard. Pretty well each mine here has its own peculiarities, and in many cases the mining of the really profitable ore in a banket mine is a more difficult problem than in a quartz proposition. John Hays Hammond is reported to have said "Damn the Rand, I don't want to stay in a country where every office-boy is a mine-valuer, give me a quartz country." Well, the office-boy mine-valuer has not exactly been a success, and much money has been lost thereby. Of course, a quartz mine has chances of enrichment that in a general way a banket one lacks. Profitable, however, surprises are still in store for those who intelligently look for them. At the Bantjes, exploration of the Main Reef Leader long considered no good, is helping to put a handsome complexion on an otherwise unhealthy looking venture. On another mine, whose name I am not at liberty to give, a re-examination of old cross-cuts has enabled the management to locate a profitable orebody from 24 to 30 inches wide assaying 30s. ($7.20) over an assumed stoping-width of 40 inches. This orebody had been frequently cross-cut at different levels. Here again the mine was nearly closing-down, but is now in a fair way to earn real substantial profits, not paper ones. So even on the older mines the pleasantly unexpected sometimes happens.

The Phthisis Commission has completed its labors and will probably among other things advise that the blasting of ore be confined by law to one single shift. This is quite as it should be, and will both be a real economy and a health preservative. A great improvement on the mines has taken place, as far as phthisis prevention is concerned. Lots more yet requires to be done to weed out the 'slackers.' And the rigid enforcement of single-shift blasting will only be opposed by incompetents or managers forced to push underdeveloped mines. And these deserve no consideration. The Government is taking strong measures against anyone convicted of breaking the dust and



Plans showing the distribution of well-defined patches or shoots of conglomerate in the Far East Rand. (A) Brakpan; (B) Nigel. The dark patches represent stoped areas; in the Nigel these correspond closely with the distribution of the conglomerate, in Brakpan with special areas of conglomerate. The two plans are drawn on the same scale and oriented alike. ..... Outcrop of reef. D = dike.
Scale approximately 1 in. = 1000 ft. (after Mellor).

smoke regulations. In many cases, however, the real offender or cause of the offense escapes. I know a case of a mine manager who took over a section of a big mine, and found tramming shifts working in smoke and dust, the men being sent down before the mine had a chance to clear itself. He called the general manager's attention to this, and suggested an alteration in the time of the shift, pointing out that this would mean a temporary falling-off in tonnage. The reply was "It will be a very serious thing for you if tonnage falls." This manager, wise in his generation, moved to another mine. Now, in this mine, another section was paid a surprise visit by a Mining Inspector. The men were working under the worst conditions possible, owing to the shift going down immediately after, and in some cases before, blasting. An enquiry was held, the general manager claims he knew nothing of the practice; in fact, knew nothing at all about such details. The manager just appointed claimed ignorance too. The mine captain, the least to blame of the three, will probably lose his ticket, and

get fined. This may be an exceptional case; still it is not altogether an isolated one.

There is little excuse even for a section manager allowing anyone to influence him in breaking the law, as he can always report to his board. Nevertheless, an unscrupulous or incompetent general manager can do, and does do, a lot of harm, by indirectly encouraging breaches of the law. Of course, if trouble occurs he pleads ignorance and always gets off scot-free.

The worst abuses occur on the big unwieldy mines that have a large number of officials, with limited powers and responsibilities. In case of trouble, some underling is sacrificed and nothing more is said or done. The best-run and healthiest mines are undoubtedly those, like the Albu group, where there is a manager responsible for everything, and in close touch with his chairman or managing director. Sir George Albu has set a good example by supporting his managers in their efforts to improve health conditions. And he has plainly intimated that any unsatisfactory health reports will hurt the individual manager's standing with the board. The phthisis question is such an important one on the Rand that you will excuse me for dilating on it.

A rather amusing echo of the last strike is being heard in the law-courts. Sir George Albu is being sued by the recently returned deportees for libel. In a speech at the Chamber of Mines soon after the strike he called them "criminals" and apparently added in the "widest sense of the word." Now they are suing him for libel; judgment is not yet given, but no evidence to justify the language was forthcoming, and Sir George by this time should have understood the English language better than to have said what he did. Apparently he wished his remarks to be construed in a "pickwickian sense." German-born though he is, he has sent his son to fight for his adopted country. Good luck to them both.

In the *Journal* of the Chemical, Metallurgical and Mining Society of South Africa for February is given the full text of E. T. Mellor's paper, 'The Conglomerates of the Witwatersrand,' from which the accompanying sketch is taken.

GUADALAJARA, MEXICO

SUBSTANCE OF A DECREE BY THE PRESIDENT OF MEXICO, INTRODUCING IMPORTANT CHANGES IN MINING LEGISLATION.

The new export and import taxes are to be effective from May 1, 1916, and the taxes on mining property, as mentioned in the decree, to be in force from July 1, 1916. Taxes are to be paid in Mexican gold coin. (American money is usually accepted at the rate of 2 for 1.)

Article 1: (A) Metals exported in the form of ore, cyanide products, sulphides, furnace products, or in whatever other form combined or mixed with substances that are not metals properly speaking, as follows: Gold and silver, 10% *ad valorem*. Other metals, 5% *ad valorem*. (See Article 7 transitory.)

The Secretary of Hacienda will fix the value of the different metals each month according to the ruling prices in the foreign markets. (This means New York quotations).

(B) Metals treated in Mexico to the point that they are only alloyed or mixed with other metals, and whatever may be their grade, are subject to a reduction of 20% on the duties given in preceding paragraph (A).

Article 2: The following are not subject to the Interior Stamp Tax. (In this case meaning not subject to export duties.)

(A) Refined gold delivered to the mint for coinage, or presented in the Government offices in exchange for silver money at the rate of 0.75 gram of fine gold for one *peso*.

(B) Gold and silver money of current coinage whether Mexican or foreign. (Nevertheless risky to attempt exportation of Mexican money.)

(C) Silver in any form, natural or artificial product when the silver is less than 250 grams per ton (1000 kg.).

(D) Gold and silver imported into Mexico, in the form of ores, cyanide precipitate, concentrates, furnace products, etc., for treatment in Mexican metallurgical plants. Within a period of four months after their importation into Mexico.

(E) Gold and silver used in Mexican industries.

(F) Samples of mineral in their natural state. (In lots not exceeding 10 kg.)

(G) Copper in ore containing less than 3% copper. Lead in ore when less than 10%. Zinc in ore when less than 15%. (This applies when an ore or product contains one, two, or three of these metals.)

Article 3: (Referring principally to metals delivered to the Mint.) Costs of assaying are only charged when the work is done at the request of the owner or by legal requirement or by Government order. Costs of melting when bars are not homogeneous, or the cost of parting is to be paid by the owner if he wishes the work done; and at a cost based on the cost of operation of the respective Government offices.

Article 4: Metallurgical establishments are subject to the common laws in all of their operations.

Article 5: Special stamps worth ₱10 Mexican gold must be affixed to each title to mining property for each pertenencia covered by the title, regardless of the mineral substance. (This applies to titles already existing and to new titles that may be taken out.)

Article 6: The annual tax on mining property shall be as follows, for gold and silver properties:

(A) 1 to 10 pertenencias, $6 per year; $2 every four months.

(B) 11 to 50 pertenencias, $12 per year; $4 every four months.

(C) 51 to 100 pertenencias, $18 per year; $6 every four months.

(D) 101 or more pertenencias at the rate of $24 per pertenencia per year, or $8 every four months.

The above amounts are for each pertenencia or fraction. (Pertenencia is a square 100 metres on each side.)

Properties other than gold and silver:

(A) 1 to 50 pertenencias, $6 per year per pertenencia; $2 every four months.

(B) 51 to 200 pertenencias, $12 per year; $4 every four months.

(C) 201 to 500 pertenencias, $18 per year; $6 every four months.

(D) 501 or more pertenencias, $24 per year; $8 every four months.

(All amounts per pertenencia and in Mexican gold coin.)

Article 7: The progressive increase is applicable when the pertenencias are of one owner and situated in the same mining district (whether the pertenencias owned are contiguous or separated.)

Article 8: State taxes shall not exceed 2% of the value of the product.

Article 9: The following material is free from import duties when for use in the treatment of ores:

Zinc in bars, filings, granulated, shavings, or in small sheets (including large sheets perforated so as to render them useless for other purposes); sulphur, alkaline cyanides, hyposulphite of soda, and nitrate of potash or soda.

Article 10: All payments to be made in Mexican gold coin.

Transitory articles: 7th. The tax of 5% on metals other than silver and gold, mentioned in Article 1, applies to copper when the New York price for that metal is less than 25c. U. S. currency per pound; when the price of copper is 25c. and up to 30c. per pound the tax shall be 6%, and when copper exceeds 30c. American currency per pound in New York, the tax shall be 7%.

(Signed) V. CARRANZA.

Dated Mexico City, May 1, 1916.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Juneau

During the first 10 days of May the Alaska Gastineau mill has been treating 6000 tons daily, assaying $1.60 per ton. This is a great improvement over the 94-cent average in April.

On May 11 the Treadwell foundry cast a 5-ton drop-hammer, the largest casting ever made in the North. It is 11 in. high and 42 in. at largest diameter, and is used for breaking large scrap castings for re-melting. On May 29 the Alaska Treadwell company pays 50c. a share.

Ketchikan

(Special Correspondence.)—About 250 men are employed by the producing mines in this district. Seven copper mines are shipping at the rate of 12,000 tons a month; three gold mines are yielding ore, and a number of gold-copper properties are being developed. The territorial mine inspector, W. Maloney, has just completed an inspection tour of the local mines.——F. B. Hyder, mining engineer and geologist for the Alaska Gastineau company is examining gold properties at Sea Level, Thorn arm.——G. M. Fripp has bonded the Cymru mine at North arm.

ARIZONA

Cochise County

Renewed activity is reported from the Bowie, Golden Rule, and Whetstone districts, the first two being gold producing areas.

The advance in silver is greatly benefiting the Bunker Hill property at Tombstone, which has increased its output of ore containing that metal and manganese. Water caused the shutting-down of the old operating company, and the present owners have not bothered much, save to pump 100,000 gal. daily for current use.

DETROIT COPPER CO.'S TAILING DUMP AT MORENCI, ARIZONA.

Gila County

At the Old Dominion the A shaft is producing over 1100 tons of ore a day, mostly from No. 12, 14, and 16 levels. The flow of water is now 7,000,000 gal. in 24 hours. The concentrator treats 700 tons, and the flotation plant 300 tons daily. Some fine concentrate is sent to the International smelter at Miami.

Development and production at the Iron Cap is reported as very satisfactory.

When No. 19 and 20 sections are working in the Inspiration mill the plant should treat nearly 20,000 tons daily. The floor area of the whole is 4 acres, against 8 acres needed for a gravity concentration plant of 7500 tons' capacity. In the mine a system of block-signals is to be installed to regulate ore-haulage.

Mohave County

In the old Stockton Hill district the Arizona Buttes Mining Co. has acquired 500 acres, developed it considerably, and is now ready to erect a 120-ton mill. Henry M. Crowther is general manager.

CALIFORNIA

Amador County

Following is the preliminary statement of the Plymouth Consolidated for April:

Ore milled, tons	11,000
Total value	$59,900
Working expense	27,136
Development	4,188
Surplus	$28,576
Other expenditure	$ 4,273

Butte County

The old Willard placer mine at Magalia has been acquired by S. D. Mesmith and W. E. Young of San Diego from F. H. Dakin. Development is to commence at once. In 1856 a 54-lb. gold nugget was found in this mine, which has been idle for 40 years.

Calaveras County

Farmers of Calaveras and Amador counties, owning 20,000 acres of land, have joined in 34 suits in the U. S. District Court at San Francisco to recover damages of $300,000 from the Penn Mining Co., which operates a smelter on the border of the two counties.

It is alleged that fumes from the smelter have destroyed crops and stock. The company has replied that it is not the gases that have ruined the crops, but poor farming.

Plumas County

At the Walker copper mine the cross-cut adit is in 500 ft., and at 440 ft. cut what is probably a parallel vein to the main orebody. The ore shows carbonate, chalcopyrite, and glance.

San Bernardino County

Although little has been written about Goldstone lately genuine development is reported, with good results. There are now seven operating companies.

The Atolia company announces that it has shut-down the Parr and East Union mines, releasing 100 men, on account of the poor showing in the bottom workings of these two mines and the collapse in the price of tungsten.

Shasta County

From the mine of J. J. Hartigan and H. T. Mecum on Mears creek, 4 miles west of Sims, 40 tons of asbestos has been railed to Oakland for sale.

Trinity County

San Francisco and Los Angeles capital, represented by W. B. Winston and C. A. March, has bonded 1500 acres of land

between Lewiston and Pokes Bar on the Trinity river. The average price was $200 an acre. Keystone drills have been prospecting for some time. One dredge is to be built at once and two later on.

COLORADO

It is reported that leading mine operators in this State are to have an enquiry into wages paid, and a re-adjustment of same, to be fair to all concerned.

Gilpin County

By means of the Newhouse tunnel the Ophir Burroughs, Pozo-Gilpin, and Gunnel mines are being actively worked. In the near future mines in the Nevadaville and Quartz Hill sections of the county will benefit by drainage through the tunnel.

Summit County

During April the Breckenridge district dispatched gold worth $50,000 to the Denver mint. The Tonopah Placers Co. has three dredges at work, and the French company, one. The latter saved a number of small nuggets, one worth $150, and other coarse gold in April.

The Wellington Mines Co. shipped 1500 tons of zinc ore and concentrate last month. Both mills, with a total capacity of 150 tons, are working. A market has been found for the iron-silver-zinc product, and shipments will be 100 tons weekly.

Teller County (Cripple Creek)

In the first quarter of 1916 the Vindicator Consolidated earned $225,000 net from 33,086 tons of ore. Developments in its Golden Cycle mine are encouraging.

On No. 19 level of the Portland the No. 1 vein is 6 ft. wide, worth from $50 to $125 per ton. Between the lowest workings and the Roosevelt drainage-tunnel there is 200 ft. of unexplored ground.

IDAHO

Custer County

Work has been resumed at the well-known Lost Packer copper mine on Loon creek. Little work is done in winter, but in summer the smelter and concentrator are operated.

Shoshone County (Coeur d'Alene)

The monthly yield of the Success zinc mine in the Nine-Mile district is 1800 tons of ore. Development at 1300 ft. is good. April profits were $90,000.

In the Carney copper mine, near Mullan, reserves are estimated at 50,000 tons. Ore is being sent to Tacoma.

The Interstate-Callahan shaft is being sunk 6 ft. daily with three shifts and four men on each.

Approximately $120,000 was paid to 4000 men in the Coeur d'Alene in the week ended May 13, the largest amount ever distributed for a week.

The Day interests have secured control of the Ray-Jefferson Mining Co. The treasury contains $100,000 to finance development and equipment. The new 250-ton mill is to be ready by July 15. Development continues good. The same people have also got control of the Basin Mining Co., operating in the Burke district, through their connection with the Hercules company.

MONTANA

Lewis and Clark County

On account of the increased scale of operations in the Marysville, Rimini, Scratch Gravel, and other adjacent districts, Helena is said to be busier now than for 20 years.

Lincoln County

After spending $40,000 in preparatory work, the Bear Creek Placer Mining Co. has commenced work 18 miles south of Libby. The steam-shovel, screening, and sluicing plant can handle 500 cu. yd. of gravel daily.

Silverbow County (Butte)

In the first quarter of 1916 the Davis-Daly company made a deficit of $27,504. Sale of 4208 tons of ore, producing 278,389 lb. copper and 17,844 oz. silver realized $42,540. Development cost $36,981, and mining $30,856. At 2500 ft. depth the ore-shoot is 380 ft. long as far as developed, with high grade in parts. A Nordberg hoist of 1000-ft. capacity, lifting 3½ tons, has been ordered. Ventilation is a serious problem.

The Tuolumne Copper Co. has increased its capital from 800,000 $1 shares to 2,500,000 of the same par value.

In the first quarter of 1916 the Butte & Superior Mining Co. had the following results:

Ore treated, tons	164,500
Zinc content, per cent	15.692
Silver, oz. per ton	6.844
Concentrate produced, pounds	90,242,000
Zinc-content, per cent	53.122
Extraction, per cent	92.855
Total cost per ton of ore	$5.61
Revenue	$4,623,143
Profit	3,554,940

In the corresponding period of last year the profit was $1,163,156, and in 1914, $337,241.

MICHIGAN

The Copper Country

April yields of Calumet & Hecla and subsidiaries are as follows, in pounds:

Mines	April	Year to date
Ahmeek	2,158,451	7,109,721
Allouez	929,960	3,262,254
Calumet & Hecla	5,709,434	24,073,838
Centennial	257,790	820,899
Isle Royale	950,580	3,768,491
La Salle	95,863	439,646
Osceola	1,783,470	6,444,503
Superior	385,034	1,140,909
Tamarack	559,374	2,310,780
White Pine	404,587	1,441,417

MISSOURI

Jasper County

In the week ended May 14 ore prices declined in the Missouri-Kansas-Oklahoma field, to an average of $88, $71, and $97 per ton for blende, calamine, and lead, respectively. The output was 7051 tons blende, 424 tons calamine, and 1297 tons lead, worth a total of $782,093. For 19 weeks the total is $16,555,409.

NEVADA

Esmeralda County

The Florence Goldfield Mining Co. has purchased the flotation plant of the Nevada Metal Extraction Co. to treat Florence's dumps. The plant will be increased to 300-ton capacity. The 50,000 tons of ore assays $5 per ton; the mine also contains 75,000 tons of $4 ore. The percentage of copper varies.

The Reorganized Booth company has declared a dividend of 5c. a share for June 6. This makes 35c. in three months, or $350,000. The money is from the sale of shares in other companies with which the Booth had apex suits.

During April the Jumbo Extension produced 2721 tons of $29.03 ore, at a profit of $25,000. Development is yielding good results. A 5-c. dividend has been declared.

Lyon County

The Nevada-Douglas leaching plant has started work, treating 250 tons daily.

At the Thompson smelter of the Mason Valley company, the 10-ton leaching plant, in charge of E. R. Weidlein and G. A.

Bragg, has treated 10 tons of low-grade oxide ore for a month, and will be doubled in capacity. The Minnesota-Nevada mine owners are sending ore to this plant for treatment.

Mineral County

(Special Correspondence.)—There is activity in the Reservation district, and several gold, copper, and silver-lead deposits are receiving attention. The Packsaddle mine is worked by Carson City people, with George L. Hedges as superintendent. An adit is being driven along No. 4 vein, showing some free-milling gold ore. It will be extended 800 ft., and is expected to cut three cross veins. Copper ore of shipping grade has been opened, and early shipments are contemplated.

The Mt. View mine is extracting free-milling gold ore through three adits and is working a small mill with water from the Walker river. Profitable ore has been opened to a depth of 200 ft. Some work is being done at the near-by Sebastopool and Reservation Hill mines.

The Yerrington Mountain Co. is shipping copper ore to Schurz, from which point it will be sent to custom smelters. The orebody is 7 ft. wide, with 12 in. of high-grade. A compressor has been installed, and driving from the Azurite shaft is proceeding with machine-drills. The shaft is being arranged for operations from the 500-ft. level.

Reservation, May 11.

The Luning district's mines shipped a total of 2500 tons of 6% copper ore in April, mostly by lessees.

Nye County

During the week ended May 13, Tonopah mines produced 9301 tons of ore valued at $192,678. The Belmont shipped bullion worth $137,092, and the Extension $89,000.——The MacNamara mill is expected to resume work in the near future, and may treat custom ore as well as its own.—At a depth of 1200 ft. in its Sand Grass claim the Tonopah company has cut the Murray vein.

Storey County

At 2500 ft. depth in the Mexican, and 2700 ft. in the Union, driving north is under way. Stopes in the latter are yielding up to $48 ore. The Mexican mill is again treating ore.——Fair ore is reported on the 2700-ft. level north in the Ophir.——The Jacket mill is kept busy.

NEW MEXICO

Socorro County

On account of the higher price for silver the Mogollon and Socorro companies at Mogollon are netting $2 extra per ton.

UTAH

All smelters in the Salt Lake valley are at capacity. The lead plants can treat 3000 tons daily, and cannot receive more ore; while the copper plants, of 5000 tons' capacity, are ready to receive ore.

Beaver County

On Sunday, May 15, about 50 mining men, brokers, and others from Salt Lake City visited the Star district. The recent developments at the Paloma and Cedar-Talisman were inspected; one is copper and silver, the other silver-lead and zinc.

Boxelder County

Working on an extension of the Lakeview company's vein the Lakeview Volunteer Mining Co. is opening 20 to 30% zinc ore at its new camp called Spelter. F. Jardine is general manager.

Summit County

Park City with its 5000 people is very optimistic as to the future on account of the high metal prices, large ore output, and increased wages.

Tooele County

From the Deep Creek district, near Gold Hill, over $5000 worth of scheelite is being shipped each week by parcel post by Wilson brothers. Others are busy looking for the mineral.

WASHINGTON

Ferry County

Present shipments from the Lone Pine-Surprise mine at Republic, which is being worked by the Republic Consolidated Mines Co. are 100 tons daily of $12 gold ore, to be increased soon to 200 tons. The 300 and 400-ft. level drifts will be extended to the Pearl vein. Work on the double-compartment shaft is progressing satisfactorily and will be continued to the 1000-ft. point. A. J. Laughon is manager. Extensive improvements are under consideration.

King County

At Van Asselt the Antimony Smelting & Refining Co. of Seattle has started operating its new smelter. C. M. Philipson is in charge.

Okanogan County

Many minerals, especially antimony, gold, silver, and tungsten are found in this county, and greatly increased attention is being directed to possibilities.

Spokane County

Work in the Loon Lake copper mine, 46 miles from Spokane, has opened a fairly long shoot of high-grade ore at 200-ft. depth, and the mine will be a regular producer in a few months.

CANADA

British Columbia

There is greater activity and more evidence of prosperity among the mining regions of this Province than ever before, and the current year undoubtedly will establish a new high record of earnings and production for the operating companies, according to Andrew G. Larsen, who is connected with the Lucky Jim Zinc Mines Co., and who recently returned from an extended tour of the different centres.

During the 9 months ended March 31 the Granby Consolidated produced 28,122,261 lb. of copper at its Anyox and Grand Forks smelters. The net income was $2,373,863. Dividends absorbed $674,933.

There is said to be an extensive mining area, almost unprospected, east of Hope, within 100 miles of Vancouver. It includes the Coquahalla river country. Two railways now make the district easily accessible, and some promising prospects are being developed.

During March the Standard Silver-Lead company made a profit of $136,943 from 1295 tons of crude lead ore and concentrate shipped. On May 10 2½c. per share, or $50,000, was paid.

Ontario

One hundred additional stamps are to be erected at the Hollinger mill, doubling the capacity, equal to 4000 tons daily.

Flotation is being tried on tailing at the Trethewey mine at Cobalt.

In April the Nipissing output was $167,446, from 119 tons of high and 6034 tons of low-grade ores. The refinery produced 708,524 oz. of silver, partly from custom ore. The higher price of the metal now permits of poor ore at several shafts and on dumps being treated.

Tailing value at the Dome Lake is now only 40c. per ton, due to the new cyanide plant.

In *The Canadian Mining Journal* for May 1 most of the space is occupied by interesting and well-illustrated articles and company reports on the operations at Porcupine. There are also notes on the Boston Creek goldfield, Kirkland Lake.

and other centres. The record of the leading producers, as reported to the Ontario Bureau of Mines, for 1915, was as follows:

Mine	Ore milled, tons	Gold recovered, ounces	Value per ton
Hollinger	334,750	156,573	$ 9.67
Dome	317,740	73,726	4.79
Acme	106,486	49,933	9.69
McIntyre-Porcupine	101,955	36,094	7.31
Porcupine Crown	46,419	29,032	12.92
Tough-Oakes	26,196	26,658	21.04
Vipond	35,899	11,871	6.83

For the whole Province 1,036,387 tons of ore was treated, the yield being 411,588 oz. of gold and 77,126 oz. of silver, with

MAP SHOWING POSITION OF PORCUPINE, KIRKLAND LAKE, MUNRO, BOSTON CREEK, AND KOWKASH GOLD AREAS.

a total valuation of $8,539,887, or an average of $8.24 per ton. The aggregate value of gold produced in Ontario to December 31, 1915, was $23,324,389. T. F. Sutherland estimates the gold ore blocked-out in mines operating in Ontario at $40,000,000. He estimates the 1916 production at $16,000,000.

YUKON

No. 1 dredge of the Canadian Klondyke company commenced digging on Hunker creek on April 17, the same date as in 1915.

Copper mines in the vicinity of Skagway are being worked full time, shipping ore to Tacoma.

The U. S. Civil Service Commission announces an open competitive examination for mining draftsman, on June 7 and 8. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Bureau of Mines, Pittsburg, Pa., at an entrance salary of from $1020 to $1200 per annum, and vacancies as they may occur in positions requiring similar qualifications.

The AMERICAN CHEMICAL SOCIETY held its 52nd meeting at the University of Illinois, Urbana, on April 18-21. Over 600 members were registered. A total of 283 papers were presented on all subjects allied to chemistry. Charles A. Herty is president.

The AMERICAN ELECTROCHEMICAL SOCIETY held its 29th meeting at Washington, D. C., on April 27 and following days. The new president is Francis A. J. Fitzgerald of Niagara Falls.

The quarter-centennial of the University of Chicago is to be celebrated on June 2 to 6.

PERSONAL

Note: The Editor invites members of the profession to send him particulars of their work and appointments. This information is of unquestioned interest to our readers.

F. M. MANSON, of Reno, is in town.

G. WOOLCOTT, formerly at Cripple Creek, is at Oatman, Arizona.

T. W. GRUETTER, of Medford, Oregon, is here on dredging business.

R. D. MONTGOMERY of the San Vicente mine, Mexico, is at Los Angeles.

ERNEST J. LOCKE is returning from Oatman, Arizona, to Hollywood, California.

EDWIN E. CHASE and son have returned to Denver from a two weeks' trip to south-western Texas.

EDWIN F. YATES has sailed for the Philippines to take a position with the Colorado Mining Company.

CHARLES B. CRONER is examining the Eldorado Gold Star Mining Co.'s properties at Searchlight, Nevada.

R. T. BAYLISS, according to latest news, is recovering satisfactorily from the injuries recorded in our issue of May 6.

GEORGE E. FARISH has been appointed consulting engineer for the Tri-Bullion Smelting & Development Co., New York.

WILLET G. MILLER and T. F. SUTHERLAND sailed on May 23 by the *Sonoma* for Sydney, on their way to New Caledonia.

CHARLES F. WILLIAMS, lately with the Chino Copper Co., at Hurley, New Mexico, is now at Cananea, Mexico, in the capacity of mining engineer for the Cananea Consolidated Copper Company.

Among those who marched in the great preparedness parade at New York on May 13 were: J. PARKE CHANNING, C. R. CORNING, LAWRENCE ADDICKS, JOSEPH RICHARDS, E. A. SPERRY, BENJAMIN B. THAYER, and W. L. SAUNDERS.

The Nevada section of the AMERICAN INSTITUTE OF MINING ENGINEERS was successfully installed at Reno on May 18. The local section commenced with a membership of over 90. The officers elected were J. W. Hutchinson of Goldfield, chairman; F. C. Lincoln of Reno, vice-chairman, and Henry M. Rives of Reno, secretary-treasurer. An executive committee was selected, composed of nine members, including the chairman and vice-chairman, and John G. Kirchen of Tonopah, Frederick Bradshaw of Tonopah, W. H. Blackburn of Tonopah, C. B. Lakenan of McGill, E. A. Julian of Reno, Governor Emmet D. Boyle of Carson, and ex-Governor Tasker L. Oddie of Reno.

During the proceedings attending the installation, addresses were delivered by Governor Boyle, J. W. Hutchinson, and W. L. Saunders. Charles Butters, Whitman Symmes, and J. C. Jones addressed the section. A discussion ensued. In the evening a banquet was held at the Riverside hotel; in this 40 members and their ladies participated. During the course of the banquet Professor Lincoln of the Mackay School of Mines delivered an illustrated lecture on the 'Evolution of Mining.' On the following day a party of 33, including Mr. Saunders, journeyed to Virginia City by automobile, stopping on the way at Steamboat Springs, where Professor Jones acted as guide to the party. At Virginia City members and their ladies were taken care of by Mr. Symmes and T. F. McCormick, who took them down the Union shaft to the 2700-ft. level and through various workings, emerging from the C. & C. shaft. Luncheon was then served at the Masonic Hall by the ladies of Virginia City, the party being welcomed by Judge Frank P. Langan. Governor Boyle replied in behalf of the Nevada section. Mr. Symmes presided at this luncheon. The party left Virginia City at 4:30 in the afternoon and proceeded to Carson, where they were received at the Governor's mansion by the Governor and Mrs. Boyle, after which the trip to Reno was completed.

THE METAL MARKET

METAL PRICES

San Francisco, May 23

Antimony, cents per pound	37.50
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	7.75—8.75
Platinum, soft metal, per ounce	$80
Platinum, hard metal, 10% iridium, per ounce	$81
Quicksilver, per flask of 75 lb.	$90
Spelter, cents per pound	22
Tin, cents per pound	50
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, May 23.

Antimony, 50% product per unit (1% or 20 lb.)	$2.00
Chrome, 40% and over, f.o.b. cars California, per ton	12.50
Manganese, 50% metal, 8% silica, per ton	12.00
Tungsten, 60% WO_3 per unit	30.00—40.00

At Boulder, Colorado, the Boulder Tungsten Production Co. is paying $50 per unit for 60% product. Grades under 20% are received at the mill. The Primos company is paying $10 per unit. The Boulder County Producers Association has been formed at Nederland to study the market and fight price manipulations. The steel interests are accused of making prices to suit themselves.

EASTERN METAL MARKET

(By wire from New York.)

May 23.—Copper is quiet and easier; lead is dull and easy; spelter is weak and neglected.

COPPER

Prices of electrolytic in New York, in cents per pound.

The fundamental reason why silver is advancing is because Europe is now on a paper basis, the various governments holding tightly to their gold.

Given exhausted stocks, high expectations on the part of producing mines, and continuous purchases arising from the necessities of coinage, enquiries which can hardly be staved off—and which emanate from several countries at one time—the situation admits of little or no modification. Any temporary lull in the demand and easing of the price would only serve to encourage speculative interest, and for that reason a reaction, when it does come, may be comparatively small and short-lived, according to Samuel Montagu & Co. of London.

Most of the Cobalt, Ontario, companies have raised miners' wages 25c. a day from May 1; all employees will receive a bonus of 25c. daily during each month in which the metal averages 70c. or more an ounce.

Silverware has advanced 25% in price in the last three months.

LEAD

Lead is quoted in cents per pound, New York delivery.

The Federal Mining & Smelting Co., operating four mines in Idaho, pays 1%, or $120,000, on preferred stock on June 6.

A bulletin including notes on the lead production of the Central States in 1916, especially Missouri, with 210,440 tons metal, has been issued by the U. S. Geological Survey.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

A bulletin including notes on the zinc output of the Central States in 1916, especially Missouri, with 136,300 tons of metal, has been issued by the U. S. Geological Survey.

American Zinc, Lead & Smelting Co.'s net profit in the March quarter was $2,255,000. Butte & Superior is earning $1,250,000 net per month. New Jersey Zinc Co.'s profit in the March quarter was $8,561,385, of which $6,650,000 was distributed. These three companies are earning a total of $58,000,000 per annum, equal to $16, $56, and $94 per share respectively.

On June 30 the Interstate-Callahan company of Idaho pays $1.50 per share, or $697,485, making $1,394,970 for 1916, and $3,952,415 since April 1915. The rate is at 60% on the capital, and 23% on the present $26 shares.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.	1916.		1914.	1915.	1916.
Jan.	37.85	34.40	41.76	July	31.60	37.38	....

June	30.72	40.26	....	Dec.	33.60	38.71	....

Tin is quiet at 48.50 to 49.50 cents.

Eastern Metal Market

New York, May 17.

Copper continues the most active of the metals, although after a brief period of activity, mostly on foreign account, it is relatively quiet. Prices are firm and forward deliveries a trifle higher.

Zinc has slumped badly and the end is not yet in sight. Buyers are showing no interest at all.

Lead strengthened a little under stimulus of foreign buying, and quotations of the various interests are now fairly uniform.

Tin is easier because of liberal arrivals.

Antimony is down to 32c., against 45c., a few weeks ago. There appears to be an over-supply, while demand is lacking.

Aluminum is quiet but firm.

In tungsten ore there has been a heavy drop in prices, but it is thought to have been checked.

In a broad way it may be said that the peak of the iron and steel boom, with its famine prices and rush to buy, was passed in March. Since then easier prices and deliveries have come to light in several products, though in the main quotations are as strong as ever. Pig-iron has become quiet. This is not surprising in view of the enormous tonnages for which contracts were entered. In metal-working machinery, deliveries are easier, but it is noticeable that as these become better, buyers become more discriminating as to what they buy. These indications are not to be taken as meaning that business is not good. It is very good, but conditions are undergoing a change, as is to be expected with the passing of the hectic war demand. Even though new business is lighter, more normal, the steel mills and metal-working industries are filled with work for the year, and catching-up with deliveries will be slow work.

COPPER

Late last week there was a flurry of activity with a fair amount of buying on the part of France, and to a lesser extent by Great Britain and Russia. Domestic consumers also bought. It led the trade to hope that another large buying movement might be under way, but this did not materialize. The market became quiet again, but prices are firmer than they were a week ago. Although relatively quiet, the copper market is still most active of any. Third-quarter electrolytic can be had at about 28.62½c., cash, New York, or 28.75c., 30 days, delivered. The quotation for June is 29.50c., and for prompt 29.75 to 30.25c. Prompt copper is easier for the reason that considerable re-sale metal is being offered, some of it by manufacturers who over-bought. While brass rods and discs are now much easier to procure than they were a few weeks ago, this is not true with sheet and spinning brass. The brass mills are not receiving any new orders of importance for munitions, but more are in prospect. Third quarter Lake is nominally quoted at 29c. The London electrolytic quotation has continued to advance, and the price cabled yesterday (the 16th) was £158. Exports this month, including the 16th, totaled 9690. The total exports in the first four months of this year were 92,286 tons, against 90,662 tons in the corresponding period of last year.

ZINC

Spelter quotations are on the down-grade, and the trade is wondering when and how the decline will be checked. Yesterday the New York quotation for prompt was down to 15.50c. and that at St. Louis stood at 15.25c. Consumers are holding strictly aloof from the market, and it is conceded that they cannot be interested while the present trend is on. They will not again take hold, in the opinion of the trade, until the decline is checked and is followed by a turn upward. The St. Louis quotation for June, on May 16, was about 15c.; for July, 14.50c.; and for third quarter, 13.75 to 14c. The lack of new war business precludes any heavy buying by the brass mills, inasmuch as they do not buy to cover such contracts until the business is actually in hand. The London quotation for spot zinc, May 16, was down to £95. American sellers have by no means lost faith in the spelter market, and insist that at least one more up-turn is logical to expect. Exports from May 1 to 16 totaled 2449 tons.

Sheet zinc is lower at 24.50c., carload lots, f.o.b. mill.

LEAD

The dullness of the lead market was broken last week by a moderate amount of foreign buying, and there are still further inquiries before the trade. Much of the buying was of Mexican lead in bond, part of which is to be manufactured here and then exported with the advantage of the drawback duty, while some of it is to be exported in pigs. The foreign activity gave the market a better tone, and the quotation of the Independent producers drew up to that of the A. S. & R. Co.—7.50c., New York. The Independents have been quoting 7.40c., St. Louis, whereas the leading interest is still asking 7.42½c., St. Louis. When prices took on a better aspect the amount of lead that was offered surprised the trade, inasmuch as under such circumstances the sellers usually wait for higher levels. Their action is taken as evidence that they have had enough of inactivity. Exports from May 1 to 16 totaled 2086 tons. The London quotation, on the 16th, stood at £33 15s.

TIN

The market shows an easier trend because of the fairly large arrivals of both Straits and Banca tin. The latter is being freely offered, and is being used by many consumers who formerly considered that Straits was essential for their purposes. On the whole the market has been dull, although on May 15 Western consumers purchased 400 tons, and did not conclude their buying. The quotation for spot on Monday, and yesterday also, was 49.25c. Arrivals of the month up to the 16th totaled 1233 tons, and there was afloat on that day 4520 tons. Government figures show that the imports of tin at Pacific ports in March totaled 774,237 lb. in the San Francisco district, and 4,511,077 lb., valued at $1,609,743, in the Washington district.

ANTIMONY

It seems almost impossible to interest consumers in antimony, despite the fact that the quotation for prompt Chinese and Japanese grades is down to 32c., duty paid. June shipment from China is quoted at 25c., c.i.f., but this is inactive also. The fact is that there is an over-abundance of antimony on the market and consumers know it, and inasmuch as their supplies are sufficient for the present they are not going to buy when there is a prospect of lower prices.

ALUMINUM

The nominal quotation for No. 1 virgin aluminum, 98 to 99% pure, stands at about 58 to 60c. per pound. An interesting fact with regard to aluminum is that because of its high price and scarcity, several of the automobile manufacturers are abandoning its use and substituting cast iron or some other metal. Some of the automobile makers have surmounted the high prices for all metals by advancing the prices of their cars, and have contracted heavily for aluminum for 1917.

The U. S. Geological Survey has issued statistics on lead in 1915. The yield from domestic ore was 537,012 tons compared with 534,482 tons in 1914, but of much higher value.

COMPANY REPORTS

HECLA MINING CO.

During 1915 this company, which operates a well-equipped mine at Burke and a mill at Gem, Idaho, distributed $565,000 in dividends. Over 6 years' ore reserves are developed, a total of 1,100,000 tons. The ore averages 9% lead and 5 oz. silver. Last year the output was 24,917,867 lb. lead and 692,444 oz. silver, from 112,646 tons treated, also 11,340 tons shipped to smelters. Lead averaged 4.8656c. per lb., and silver 50.38c. per oz. The income was $1,034,487. Costs were $2.648 per ton. The profit was $461,752. James F. McCarthy is general manager.

MAGMA COPPER CO.

This company operates a mine at Superior, Pinal county, Arizona. The known orebodies occur in a strong fault-fissure filled with porphyry and cutting diabase, quartzite, and limestone. Development in 1915 covered 5619 ft. A new three-compartment shaft was completed and sunk from the main 200-ft. adit-level to 30 ft. below the 1200-ft. level. Work below 800 ft., in diabase, has shown commercial ore on all levels. In the low ground zinc-lead-silver ore has been opened, distinct from the copper ore, there being 10,000 tons assaying 14% zinc, 4% lead, and 10 oz. silver. The mill is to be arranged to treat this ore. Other reserves consist of 90,000 tons containing 6.65% copper, 6.75 oz. silver, and 0.029 oz. gold.

The water concentration and oil-flotation plant treated 55,463 tons, averaging 5.21% copper, and 6.04 oz. silver, with 86.765% recovery, yielding 15,039 tons of 16.67% copper and 19.05 oz. silver concentrate. Nine hundred tons of carbonate ore assayed 8.2% copper, 4.55 oz. silver, and $1.20 gold per ton. The yield of refined copper was 6,046,459 lb., at a cost of 6.82c. per lb.

Metals sold, including $208,658 from precious metals, realized $1,023,676. The operating profit was $670,886, less $59,157 for depreciation. Two dividends absorbed $240,000. The year ended with a balance of $405,797, compared with $34,068 in 1914. W. C. Browning is in charge.

ISLE ROYALE COPPER CO.

By the end of August 1915 the three units of the new stamp-mill, to replace the burned plant in December 1914, were treating 2000 tons of ore daily. Everything is motor-driven, power coming from a 600-kw. low-pressure turbo-generator. During the erection of the plant ore was sent to the Franklin and Tamarack mills. Wages were raised and bonuses given during 1915. Development totaled 14,446 ft., against 9694 ft. in 1914. The deepest shaft is 3211 ft.

Results were as under:

	1915	1914	1913
Ore hoisted, tons	799,890	541,373	371,774
Waste discarded, per cent	15.0	12.4	15.4
Ore treated, tons	680,270	474,349	314,679
Copper per ton of ore, pounds	13.7	13.9	13.2
Refined copper yield, pounds	9,342,106	6,601,235	5,887,000
All costs, cents per pound	14.94	13.05	18.81*
Revenue from copper	$1,715,251	.....	.....
Silver sold	38,974	.....	.....
Profit	489,277	.....	.....

*Of this cost, 14.94c., nearly 2c. per lb. was the expenditure of $183,293 on re-building the mill, and charges at shafts. Assets include cash $304,265, metals on hand $790,524, and supplies $135,865, a total of $1,230,654. Current liabilities total $856,164. With the balance from 1914 and the 1915 profit the surplus is $1,339,848.

MINING DECISIONS

MINERAL LEASE FROM ONE CO-TENANT—EFFECT OF PARTITION.

One who leases mineral rights from one of several co-tenants of a certain tract is not entitled in a subsequent partition suit to set up any claim in kind as against all the co-tenants. The lease will automatically expire when partition takes place. The right of the lessee to share in the lessor's portion of the proceeds of the partition sale was not passed on in this case.

Spence *v.* Lucas (Louisiana), 70 Southern, 796. February 7, 1915.

OIL AND GAS LEASE—COVENANTS

In an oil and gas contract which amounts to a conveyance of an interest in the land, and not a mere rental contract, the agreement of the original lessee to pay 50 cents per acre for a six months' extension of time for beginning operations is not a covenant running with the land, and is therefore not binding on an assignee of the contract. A reservation of title to one-eighth of the gas and oil is a covenant running with the land.

Pierce Fordyce Oil Association *v.* Woodrum (Texas), 183 Southwestern, 12. February 19, 1916.

OIL LEASE—EFFECT OF CONVEYANCE OF LAND LEASED

A deed conveyed certain oil and gas lands with a reservation of royalties under an existing lease. Prior to the expiration of the lease the grantee renewed it for a period of years upon stipulated rentals. Held, upon suit by the grantor against the grantee for a recovery of equivalent royalties that there was nothing on which his claim could be based, as no well has as a matter of fact been drilled, and no royalties due to anyone; and that the grantee had acted within his rights in renewing the lease.

Bond *v.* Priest (West Virginia), 88 Southeastern 114. February 29, 1916.

MINING CORPORATIONS—FEDERAL INCOME TAX

Mining companies are not denied the equal protection of the laws, nor deprived of their property without due process of law, contrary to the Constitution by the Federal income tax provisions which limit the deduction for depletion of ore deposits to 5% of the gross value of the yearly output at the mine, or by the provisions which give certain individuals and non-profit organizations exemption from various provisions of the act which are made to apply to corporations alone. The tax in question is held to be in the nature of an excise tax and not a property tax.

Stanton *v.* Baltic Mining Co. (U. S. Supreme Court), 60 U. S. L. Ed., 278. February 21, 1916.

PROSPECTING RIGHTS UNDER THE LOUISIANA CODE

Held, that under the laws of Louisiana the right to prospect and explore for oil and gas is an incorporeal right which may be conveyed by the landowner, without obligating the grantee to drill wells or perform any other condition than the payment of certain rentals. Nor will the Court inquire as to the sufficiency of the considerations where rentals substantial in amount are called for.

Saunders *v.* Busch-Everett Co. (Louisiana), 71 Southern, 153, February 21, 1916; 70 Southern, 78, February 7, 1916.

Note: It is interesting to observe this late expression from the Louisiana Supreme Court as a principle which has long ago been regarded as established in practically every other State.

EDITORIAL

T. A. RICKARD, Editor

JAMES J. HILL was not only a railway 'magnate,' he was a railroad builder; he was not only a financier, but a pioneer of industry; not only a rich man, but a useful citizen. Few men employed their wealth so beneficently. These to his memory.

THE purchase of three ore-carrying vessels, of 6500 to 7000 tons apiece, by parties allied with the Guggenheims is reported from New York. Two of them are to be used in South American business, aiding the Chuquicamata and Braden mines; the third will carry supplies of metal to Europe.

METAL markets reflect peace talk, re-sales of supplies bought on a rising market, and timidity concerning the immediate future. Our weekly report will be found interesting. It expresses the opinion of one detached from the metal-selling brokers and speculators. Foreign buying has been less in evidence, especially in lead and zinc. We expect a recovery when peace rumors have faded into the smoke of renewed battle. The time for peace is not yet.

A QUESTIONNAIRE circulated among 4500 men of affairs throughout the country elicited replies from 1710, of whom 696 favored military intervention in Mexico and 653 were opposed to it; protection of American citizens in foreign countries was deemed essential to the extension of trade by 1155 and non-essential by only 181; that business would be directly affected by peace in Europe was the opinion of 728, while 750 said No; 'preparedness' was endorsed by 1306 and opposed by 78 only.

SPEAKING of the apex law, it is unfortunate that American engineers were influential in getting the extra-lateral right embodied in the Rhodesian code for locating mining claims, instead of copying the Mexican and Australian regulations. In consequence, the Globe & Phoenix Gold Mining Co. is having a severe dose of litigation with its neighbor, the Amalgamated Properties of Rhodesia, in regard to its right to follow a lode beyond the side-lines vertically extended. As the workings already reach to 21 levels, on veins that join or cross each other at intervals, it is easy to imagine the tangle of fact and theory developed by the law-suit. Incidentally, the suggestion was made, by one of the parties to the case, that an independent engineer be sent to Rhodesia by the Court to advise concerning the facts in dispute. This suggestion was opposed by the other side, presumably on account of uncertainty as to what engineer would be selected for the task. Of course, all expert witnesses ought to be 'independent,' that is, chosen and paid by the Court. That is a reform urgently needed in this country also.

FLOTATION is to be used on a large scale at Goldfield, as is indicated in the review of mining in Nevada contributed by Mr. R. L. Richie. The copper content of the ore in that district favors flotation, because payment for copper at nearly 30 cents per pound goes a long way to meeting the cost of marketing the concentrate. At Tonopah, however, the ore is relatively free from copper and other cyanicides, save in one stope in the Tonopah Extension mine, where an ore unusually rich in copper is exposed. While an extraction of 90 to 92% by flotation is practicable on sulphide ores, the marketing of the concentrate represents 10% of the assay-value, making the net return 81%, while from the extraction by cyanidation—also 90 to 92%—only 1.6% has to be deducted for the cost of marketing bullion. In other words, flotation is a concentration process, cyanidation a process of direct extraction.

AMONG the great mines uncovered during the present decade the Hollinger, at Porcupine, takes an honorable place, not only for its dividends but for the high character of its management. We note that this enterprise is to be enlarged by a consolidation with the Acme and Millerton mines, of which the former produced $900,000 in 1915 as compared with the Hollinger's output of $3,000,000. The Millerton is a smaller property near-by. It is estimated that the ore reserves of the Acme and Hollinger, to 800 feet in depth, will amount to 5,594,570 tons containing $48,196,390 in gold. But the diamond-drill has proved that several of the veins continue ore-bearing to 1400 feet in vertical depth, so that the possibilities of production are about twice those already proved probable. The improvements now being made in the mill will give it a capacity of 1900 tons of ore daily, and an extension of the plant as planned for the next year will increase the capacity to 3500 tons, equal on average ore to an output of about $25,000 daily.

CHINESE coins in bulk have been melted by the Japanese in order to make the most of the high price now being paid for the copper and zinc they contain. The Chinese government has prohibited the export of this currency, but the embargo is evaded by melting the coins in China and shipping scrap metal to Japan. The coins are mostly of very small denomination, because the trifling individual purchases of a dense population,

in a country where the majority of the inhabitants are poor, require a great proportion of minor coins. Many of them have a square hole in the centre, both to economize metal and to facilitate stringing them on a belt for wearing around the body. The *li* contains 25% zinc and 70% copper; when melted, such coins to the face value of 27 *yen* Japanese will yield, at the present high price of metals about 12 *yen* worth of zinc and 29 *yen* worth of copper. A *yen* is equal to half a dollar. The operation therefore is profitable. The recent export of copper and copper products from Japan to Russia has far exceeded the rate of production of the Japanese mines. The difference is said to have been supplied by the melting of Chinese coinage. We note that the demand for copper in Japan has led Japanese committees to visit Australia to arrange for purchases there.

IN the advertisement annex of our last issue we note two pages of reading matter. We happen to know about the subject therein discussed because Mr. R. W. Sloan came to us complaining of a reference made to his company, without the mention of its name, in a contribution to discussion. We told him that it did not seem proper to give much space to an incidental question not related to mining, so he said he would pay for the requisite space to obtain the publicity that he desired for his explanation. No line of reading matter being for sale, we introduced him to the department of advertising, where no space is gratuitous. The episode is worthy of mention because we find many people not fully aware of the value of publicity and of the proper way to obtain it. 'Write-ups' and 'reading notices' we abhor; they are sneaking impositions on the reader—not to mention the publisher—and therefore they irritate rather than interest him. It is sound business and it is good sportsmanship to buy publicity where it is for sale honorably and where the reader is prepared to give it respectful attention. The ante is part of the game.

'COMMERCIAL ORE' and 'commercially mineralized' are terms coming into frequent use in the West. They constitute contributions to current jargon and in no way enrich the language of technology. 'Commercial' means relating to 'commerce,' which is the exchange of products. A mineralized mass in the ground is not the subject of commerce because it is not exchangeable until it has been mined and otherwise submitted to preliminary treatments, usually of great complexity, as, for example, that undergone by an ore of copper before the refined metal is finally made ready for the market. A commercially mineralized mass is a mass of metalliferous rock that can be exploited profitably; in short, it is 'ore,' neither more nor less. The use of the adjective 'commercial' was introduced by verbose reporters and illiterate promoters, it is pure jargon, and should be taboo among engineers and others desiring precision. It all comes from the misuse of the word 'ore': the application of it to what is not ore, in untechnical prospectuses and flamboyant reports. If we could school ourselves to use such basic terms as 'ore,' 'cost,' and 'profit' thoughtfully and accurately, we should, merely by so doing, kill a whole lot of chicanery, tomfoolery, and misunderstanding in mining affairs.

DISCUSSION this week includes a friendly endorsement of Mr. Burch's idea, for helping American boys in the mine, from Mr. D. M. Folsom, Professor of Mining in Stanford University. Mr. H. L. Layng contributes some interesting notes on a subject of timely interest, namely, the cyanidation of flotation concentrate, bringing out the point that oil is not the cyanicide but ferrous salts made by oxidation of pyrite. Mr. John B. Platts writes concerning the geology of Oatman, supplementing the articles by Messrs. Howard D. Smith and Frank H. Probert previously published by us. He argues that the gold-bearing ore in that district is a primary deposit from ascending solutions, indicating therefore that processes of secondary enrichment have not played an important part. Against this, however, is the fact that the richer orebodies do not outcrop, having been cut at depths between 300 and 500 feet. We understand that the water-level is between 200 and 350 feet below the surface and that no sulphide, or pyritic, ore has been found in the Tom Reed mine down to 1185 feet. Apparently, as is not uncommon in the desert region, oxidation extends to a considerable depth.

FOREIGN domination of American metal continues to receive attention. The Federal Trade Commission in a recent report states that "for years the copper trade of the world has been ruled by a vast German metal-buying organization centred in the Metallbank and Metallurgische Gesellschaft of Frankfort on the Main." Yet the United States produces more than half the world's output of copper. As regards silver, this report says that "four London firms, known as the Fixing Board, daily set the price of silver for the world." Yet the United States produces 30% of the world's annual production of that metal. The Commission concludes that "these foreign combinations constantly make the individual American producers bid against each other, and are thus able to buy at prices near or below the cost of production. By similar means and the manipulation of the foreign future markets the German metal-buying combinations over a series of years have bought millions of tons of American copper at prices averaging nearly a cent per pound below the prices paid by American consumers." Finally, this report gives a warning: "If American business men are to make the most of the great opportunity now before them, are to build securely in foreign trade, and are to avoid disaster in the shock of the stern and determined competition that will doubtless follow the War, they must at once perfect the organization demanded by the conditions of international trade." We do not apologize for the number of these quotations, they come from a source compelling respect, and they deal with a matter of vital moment. As we have suggested before, the American

Institute of Mining Engineers or the Mining and Metallurgical Society of America could do a signal service to the mining industry by appointing a committee to investigate metal-selling methods at New York. They could gather a great deal of information of practical value to mine operators and they could prepare the way for the establishment of a real Metal Exchange.

FIFTY years of mining activity on its lands is to be celebrated by the Calumet & Hecla company of Michigan, although the present corporation was not organized until 1871. The Quincy mine at Hancock, whose pure copper is famous for the making of melodious church-bells, was in operation before the Calumet & Hecla lode was discovered, as was the old Huron mine at Houghton, now the Isle Royale. But the greater activity of the early days of copper mining on Keweenaw peninsula was centred northward on the point around Eagle River, ten miles beyond Calumet. In those days, before the railroads, the copper concentrate was loaded into boats along the shore of Lake Superior for shipment to Detroit. It is in this historic part of the district that Mr. Thomas F. Cole has been acquiring large holdings of land for exploration by the Keweenaw Copper Company. Much interest is being taken in the recent acquisition, by the same group, of the 1880 acres belonging to the Seneca Copper Company, lying north of the successful Ahmeek and Mohawk mines. Mr. W. J. Uren has stated in a recent report that the land contains the extensions of the Calumet & Hecla, Kearsarge, and Allouez conglomerates, and the Osceola, Pewabic, and Kearsarge amygdaloid lodes. These efforts to revive copper mining in an old district are rendered peculiarly interesting by the fact that the locality was the boyhood home of Mr. Cole, as of several other mining men with Cornish affiliations.

The Purchase of Machinery

At a recent meeting of the Engineers' Society of Western Pennsylvania, Mr. George A. Orrok, a mechanical engineer in the employ of the New York Edison Company, contributed some interesting remarks on this subject. "The purchaser of large machinery," he said, referring to a typical case of an engineer acting for a company "must be as broad as is consistent with his knowledge, reasonably quick in making decisions, and of judicial mind. Such an engineer will not take up fads, and will not be frightened by cost in block, knowing that it is cost per unit of output that counts in the result." According to Mr. Orrok, there are three principal methods for the purchasing of large machinery. The first he calls the 'English' method, the second may be styled the 'American,' while the third is a combination of the other two, and is stated by Mr. Orrok to be the best.

In the first method, "the purchaser's engineer prepares detailed plans and specifications on which bids are taken, an award is made, and the successful bidder builds the apparatus." This places responsibility for everything but material and workmanship upon the purchaser's engineer, who is therefore unhampered by any consideration other than that of designing apparatus to meet the requirements exactly. This course, however, adds enormously, and in the majority of cases unnecessarily, to the first cost, because new patterns and drawings must be made; moreover, it involves 'taking a chance' upon the skill and experience of the engineer as a designer of apparatus upon which he may not have specialized to the same extent as the manufacturer.

The second, or American way, so-called, is to place the responsibility plump on the manufacturer. The purchaser, or his engineer, furnishes a specification "setting forth the conditions of the problem, the end to be sought, and the sizes to be observed." In addition, economies, with guarantees as to performance and delivery, are required, as well as the customary bonus-and-forfeit clauses. This method, according to Mr. Orrok, "usually secures a machine not quite fitted for the work and a set of construction details adapted from some other type of apparatus. The minor economies may be up to guarantee, and usually are, but the over-all economy is not secured in the way it should be. The manufacturer will likely furnish apparatus not quite up to the state of his art, as he will be afraid to use his latest knowledge to any extent for fear it will not please the purchaser." As to the third method for the purchasing of large machinery, "it should be borne in mind that the best engineering is one man's work, although he should have many advisers." In the combination method, this end is achieved as follows: "The purchaser's engineer prepares a skeleton specification on which a series of consultations take place, in which the entire problem is gone over with the engineers of the various bidders. During these consultations, the specification undergoes changes, and is added to until it is no longer a skeleton. Sometimes only one bidder may be selected, or it may even be found necessary to start all over again."

Anybody even slightly familiar with American manufacturing conditions will perceive at once the extravagance of the first method. Every engineer is to some extent a faddist, and loves to ride his own hobby. There are comparatively few engineers in private practice to whom could be entrusted the design of large machinery, meaning apparatus costing over the $100,000 mark, and of those the majority are under retainer to the big corporations. The design of large machinery, as well as of small machinery is a highly developed specialty; it is a branch of engineering requiring knowledge of every department of manufacture as well as familiarity with the conditions to which the machinery is to be applied after manufacture. The average consulting engineer or advisor to the operator is seldom a manufacturing specialist, and when he attempts to act for his clients in any direction away from his specialty, the odds are all in favor of his making a blunder. Any departure from

established standards adds enormously to the manufacturing cost, in fact, many machinery houses will decline to make special apparatus of any kind unless the consideration is a large one. For the purchaser's engineer who insists upon trivial or inconsequential changes we have nothing to say, except that he exists in every community, and is a nuisance alike to the manufacturer and the operator. The second method is better than the first, but not very much. This is what is commonly called by the consulting engineer, "machinery-house engineering," by which the buyer is popularly supposed to succumb to the wiles of the smooth-tongued sales-engineer and buy a lot of stuff that he does not need, or that proves with use to be unsuited to the conditions of operation. We need not discuss this method. The third, as Mr. Orrok says, is the only rational one, whether in the purchase of large or small machinery. The more skilled the engineer for the purchaser, the more carefully he examines into the characteristics of standard apparatus in order to be sure that existing designs are not suited to his conditions before attempting to devise something on his own account. The engineer exerts a necessary check upon the manufacturer, for manufacturers also are faddists, and each has something 'exclusive' with himself that he is pushing as hard as he can, and which he is sure possesses merits that are not to be found in the apparatus made by his competitor. Taking them as a class, manufacturers have a keen sense of responsibility, and will go to great lengths to ensure the selection of the right apparatus by the purchaser. When things go wrong, it is, in the mind of the purchaser, invariably the fault of the manufacturer, in which opinion the purchaser's engineer enthusiastically joins him. Knowing this, the wise and experienced manufacturer takes care to fortify himself throughout all the steps of a negotiation, and will not become responsible for the performance of any piece of apparatus except as specifically stated in the contract. Blanket guarantees are not made by the initiated; a crusher is never guaranteed to crush so many tons per hour, but so many tons per hour to pass a ring of specified size and having a definite power consumption under these conditions. In matters of this kind there has been a steady growth of common sense, the product of experience and a realization of the fact that good business must be mutually profitable.

Molybdenum and Tungsten Steel

An erroneous impression prevails that molybdenum is being much sought at the present time as a substitute for tungsten, and in consequence there has been excessive activity in the search for deposits of that metal. About ten years ago molybdenum was tried fully by progressive steel-makers in this country, and an encouraging degree of success was attained, but the price of the raw material mounted so rapidly as to become prohibitive, the output of pure ore and concentrate being insufficient to supply an active market at figures stimulative to a continuance of the demand. Another factor of importance was the existence of the Halcomb patent—issued in 1903—which completely controls the manufacture of the best grades of molybdenum steel, the range covered by this patent being the use of quantities of molybdenum from 6 to 15% in steels containing under 1.2% carbon and less than 2% silicon, as well as covering the use of chromium in practicable amounts in conjunction with steels of the composition specified. The right to use this patent, enjoyed by the Crucible Steel Company while Mr. Halcomb was president of that corporation, gave promise of creating a demand that would have necessitated further study of the metallurgy of molybdenum to overcome the difficulties and high cost of refining in order to make it available in competition with tungsten. On the retirement of Mr. Halcomb from the Crucible Steel Company the validity of the patent was tested, and the decision sustained the rights of the patentee. Since then the only use that American steel-manufacturers have been able to make of molybdenum has been in alloys not covered by that patent, and such uses represent only an unimportant consumption. In England molybdenum is employed to a small extent, but the use of it is not general, and during the present war the British Admiralty has rejected offers of the metal from many parts of the world. The commandeered Australian supply has been adequate for home needs. The French have made a thorough study of molybdenum-steel, and they make large quantities regularly. The Germans also have developed the practice of steel-hardening with molybdenum to a degree equaling that of the French. The oft-repeated statement that a given quantity of molybdenum will harden twice as much steel as the same quantity of tungsten is only partly true. In the finished steel products of equal efficiency such a ratio between the two hardening metals, as shown by analysis, is approximately reached, but a wastage of molybdenum takes place in the process of manufacture, making the actual consumption, to obtain similar results, about equal. As a substitute for tungsten, therefore, molybdenum must enter the market on a basis of even competition as to price, and in normal times the actual selling-price of tungsten in the form of ferro-tungsten is about 65 cents per pound for the contained tungsten. Molybdenum must accordingly be placed on the market at about 65 cents per pound in the ferro-compound, and it must show no trace of copper, lead, or arsenic, while the phosphorus may not exceed 0.03%. The remarks of Gin in his treatise on the rare metals are still applicable: "The manufacture of steel will absorb easily and voluntarily a considerable quantity of ferro-molybdenum if the price is kept at acceptable figures. The ores should be better exploited on a large scale, creating a stable market and a steady foundation for the industry." Upon the expiration of the Halcomb patent the use of molybdenum in America is certain to receive a sudden stimulus, since that metal is more abundant than tungsten, and the exhaustion of the richer tungsten deposits will maintain tungsten at a higher price than before the War, except in the face of a rival.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The American Boy and the Mine

The Editor:

Sir—In your issue of May 13, Mr. Albert Burch discusses the future supply of trained miners and advances the suggestion that schools be established in mining centres where, with the co-operation of the operating companies, the younger employees should have an opportunity to study the theory of mining and its practice in other districts. I wish to express my hearty approval of this suggestion and to offer on behalf of the mining department of Stanford University any possible assistance which can be given to the initiation of such a plan into actual practice.

There may be some question as to the amount of practical assistance that any mining school can give to such a scheme, but the co-operation Mr. Burch suggests in planning a course of study and in recommending young graduates who will have the experience and judgment to conduct such courses, can certainly be given. Also wherever the mining districts are within reach of a university certain members of the teaching staff of the mining school will be glad to give their aid, at least in starting instruction. The lectures which they may give to the men from underground will necessarily be simpler and more elementary than those given in the university class-rooms, but the enthusiasm behind the work will be no less. The idea of the modern university is service to the community. This is well exemplified in the School of Agriculture at the University of California.

If the mining schools of this country can be of real service to the mining profession by helping in the training of shift-bosses, foremen, and superintendents, and through helping to provide such opportunity encourage American boys to follow mining, then that is part of their mission.

D. M. Folsom.

Cyaniding Flotation Concentrate

The Editor:

Sir—In reference to an article by Mr. Paul W. Avery appearing in your issue of May 6, I offer the following suggestion:

It is quite possible that the great difference in the amount of cyanide consumed between the tests run on raw (oiled) flotation concentrates and those run on alkaline-treated and water-washed flotation concentrates is not due to the oil being a cyanicide but to a cyanicide, such as a ferrous salt, contained in the concentrate. In flotation the concentrate is coated with a film of oil that would prevent the oxidation of a ferrous salt contained in the so-coated concentrate; upon treating such a concentrate with an alkaline cyanide solution the ferrous salt would be free to react with the cyanide to form ferrocyanide compounds, thereby causing a consumption of cyanide relative to the amount of ferrous salt present. Treating the concentrate with alkalies and washing would cause the removal of the oily coating from the concentrate, thereby permitting oxygen present in the water or atmosphere to react with the ferrous salt to form a ferric salt, which, in the presence of caustic alkalies, would be ferric oxide. This does not react with cyanide, therefore such an alkaline-treated concentrate would not cause a material loss of cyanide through the formation of ferrous-cyanide compounds when it is subsequently treated by a cyanide solution.

The concentrate produced by a concentrating table is considerably oxidized during the process and it is also considerably washed, which would cause removal of much of the soluble ferrous salts; therefore, such a concentrate so produced would consume less cyanide than an otherwise similar concentrate produced by oil-flotation. The actions of ferrous salts corresponding to my suggestions are shown in the following tests, which I made on an ore containing both ferrous sulphate and ferrous sulphide. The dry crushed ore was divided into three equal parts. Part *A* was treated direct with cyanide solution containing lime; part *B* was treated with water and lime for three minutes by air-agitation, then lump cyanide equivalent to the amount contained in lot *A* was added to the test; part *C* was washed with alkaline water, then treated with cyanide and lime solution as in the case of lot *A*. All three parts were subjected to 24 hours air-agitation, lime and cyanide being added to maintain all three solutions at the same strength. The results were that in lot *A* the formation of ferrous-cyanide compounds (both soluble and insoluble) caused a consumption of 45 lb. KCN; in lot *B* the same cause resulted in a 0.2 lb. KCN consumption; and in lot *C* the same cause resulted in a 10 lb. KCN consumption per ton of ore. The consumption of cyanide due to other causes that were actually determined are not included in the amounts above given. The figures are based on the actual cyanide found in the form of ferrous cyanide in the solution and ferric or ferrous cyanide in the tailings.

In the particular case quoted by Mr. Avery, ferrous salts may not have been present, but other cyanicides that could be overcome by oxidation, alkaline treatment, and washing may have been present. I only offer the foregoing suggestion as a means for citing a possibility, and I believe it is worth consideration.

H. R. Layng.

San Francisco, May 10.

Geology of Oatman

The Editor:

Sir—I have had occasion to read a number of reports and articles on the geology of the Oatman district, and so far have found no two writers who agree on the essential points. The following notes are from careful observation in the field.

The basal formation of the district is a pre-Cambrian complex consisting of granite, gneiss, gabbro, and many variants of these and their related schists. Lying unconformably on the basal complex is a series of Paleozoic sediments consisting of highly metamorphic limestone and shales. This formation is usually tilted at high angles. It was subjected to a long period of erosion and only fragments are left.

Lying unconformably on the Paleozoic limestones is the Older Andesite, which is a series of andesitic tuffs and breccias laid down, in part at least, under the sea. This is shown by the fact that in some places limestone and lime-shale are found bedded with the Older Andesite. An occurrence of this kind may be seen near the shaft of the Gold Range mine.

The Older Andesite dips eastward at from 15° to 20°. The upper surface is one of erosion and is extremely irregular, indicating the existence of a hilly landscape before the pouring out of the overlying lavas. In general, this erosion surface has much less dip than the bedding-planes. In the upper layers the tuffs and agglomerates give place to lava-flows with intercalated beds of tuff. A good example of this phase may be seen at the Oatman Leader mine.

The original structure of the Older Andesite has been greatly obscured by metamorphism induced by later intrusives and crustal movements. The rocks have been partly re-crystallized and have developed marked porphyritic structure.

Above the Older Andesite is the "Green Chloritic Andesite" of Schrader, and regarded by him as an intrusive. Flow structure and amygdaloidal bands are observable in this formation in many places, indicating surface flows. It is undoubtedly intrusive in the Older Andesite in places, since it had to pass through the older formation in order to reach the surface. Hence the Green Chloritic Andesite is probably an extrusive, that is, a series of andesitic lavas poured out through fissures in the Older Andesite and covering the then surface in the neighborhood of Oatman. This formation is quite thin a short distance west of the town and appears to grow thicker toward the east. Since its lower contact is extremely warped, it is impossible to predict the thickness of it at a given point. However, it does not seem probable that the total thickness is anywhere over 400 feet.

Lying unconformably above the Green Chloritic Andesite is another series of andesitic lavas having a more acid composition and grading into latites. These are known as the Later Andesites. They dip eastward at about 1°. Above these, and conformable with them, are flows of rhyolite that in most places cap the summit of the Black range.

Extensive fissuring and faulting accompanied the volcanic activity, and many dikes being formed correspond ing in composition with the various lava-flows. Thus the older dikes are andesitic in character and do not cut the Later Andesites. Dikes of buckskin-colored rhyolite are a prominent feature of the landscape and they cut everything but the upper rhyolites.

The most important ore-producing veins, such as those found in the Tom Reed, United Eastern, and Big Jim mines, are found in a complicated series of fissures extending along the base of the range in a north-westerly and south-easterly direction. Part of these fissures strike nearly N45° W, and others strike about N60° W. This relation produces many intersections and large orebodies are found near many of the crossings. The veins all dip steeply to the north-east in this belt.

The vein-filling was originally calcite and contained little gold. Later activity, probably induced by the rhyolite intrusions, re-opened the fissures and part of the calcite was replaced by quartz with some adularia. The gold occurs principally in hematite (pseudomorphic after pyrite) in the quartz.

The larger orebodies are not found on the surface but appear at depths between 300 and 500 ft. Some geologists have reasoned from this that the gold has been leached from near the surface and deposited as secondary enrichments below. It is evident from the nature of the gangue that acid solutions could not exist and hence the theory of W. H. Emmons cannot be applied. Except for the oxidation of the pyrite, there is no evidence of the action of surface-water on the ore. Therefore I believe that the ore is essentially a primary deposit formed by hot ascending water. The calcite came from the andesitic magmas with possible contributions from underlying limestones, and the quartz and adularia came from the acid magmas.

Although the veins cut the Green Chloritic Andesite, it is probable that the important orebodies occur in the Older Andesite because they are found at depths below 300 ft. and, as was noted above, the Green Chloritic Andesite cannot extend much deeper than 300 feet.

The belt, or zone, above described does not extend over 4 miles long by 2 miles wide. The remainder of the Oatman district is still in the prospect stage, and deductions as to its geology cannot be made satisfactorily at this time.

John B. Platts.

Oatman, May 4.

Surficial Indications of Copper—II

By Frank H. Probert

THE relationship of physiography to ore deposits is important, but in many districts the details of it are difficult to determine. Each of the complex changes in the physical history has its effect, and, for the formation of an ore deposit, there must be a fortunate combination of many favorable factors working harmoniously together, the absence of any one of which may prevent sufficient concentration to make a mass of ore.

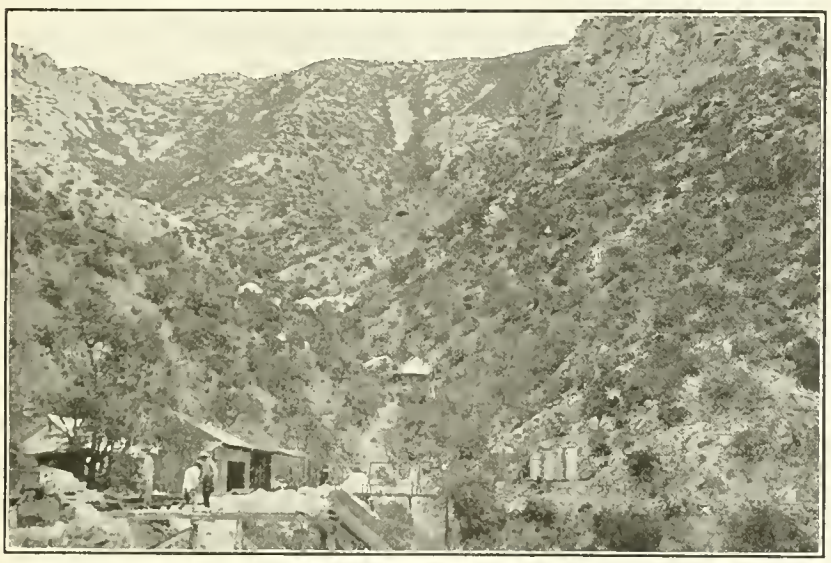

FIG. 9. RUGGED TOPOGRAPHY, 3 R MINE, PATAGONIA, ARIZONA.

The nature and genesis of an ore-deposit affect the topographic expression of the outcrop. It is, of course, necessary to distinguish between present contours and those of the mineralizing period. Elevated areas are frequently the result of comparatively recent orogenic movements, of recent fracturing; hence processes of oxidation are seldom advanced. Precipitous slopes mean rapid run-off. Gravitative stress may cause a constant widening of fractures.

Ores of igneous origin, where concentrated by later processes of oxidation and precipitation, may be sought on the middle or lower slopes of mountainous areas. However, the slow downward migration of the belt of weathering furnishes the final favorable condition for the accumulation of secondary minerals by descending waters. At a recent meeting of the San Francisco section of the American Institute of Mining Engineers, Dr. Bailey Willis presented some broad generalizations showing the distribution of mining districts around the periphery of plus areas of elevation on the American continent. This relationship is particularly well shown in the lead-zinc mines of the Ozark uplift, in the metal mines of Montana, Idaho, Utah, and Nevada, and on the western slopes of the Sierra Nevada and the Andes.

The relative hardness of the rocks, as well as the topography and rainfall, determines the amount of erosion. A brecciated vein, silicified shear-zone, or metamorphosed limestone, will be more resistant than the enclosing rock and will weather out conspicuously in the landscape. In looking over a new district, all unusual features, such as steep scarps, rock-ribs, 'blow-outs,' and sudden changes of color, should be investigated.

The longer the period of time that the mineral deposit has been subjected to surface influences the more advanced will the alteration be, and, other things being equal, the greater are the possibilities of an extensive zone of enrichment below. Most of the chalcocite bodies already exploited on the North American continent belong to early Tertiary time. The end of this geologic period was marked by a general adjustment of the earth's crust attendant on protracted volcanism. Many of the orebodies were faulted, fractured, or crushed by tectonic movement, initiating a period of vigorous oxidation. Freedom of circulation is essential for solution, precipitation, and consequent concentration.

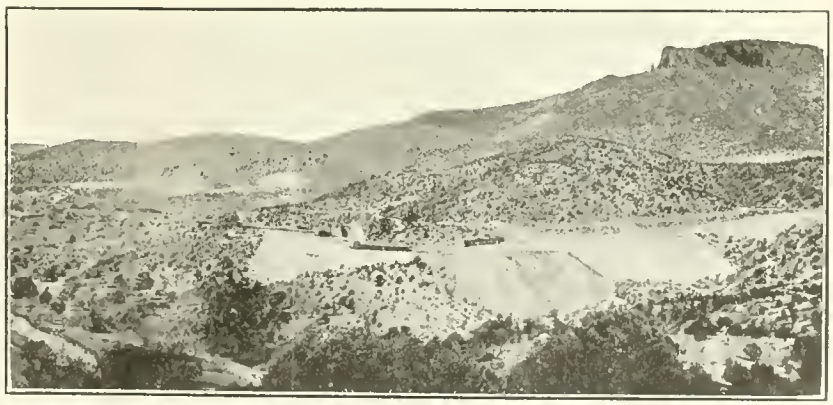

FIG. 10. ROLLING TOPOGRAPHY, CHINO COPPER CO., SANTA RITA, NEW MEXICO.

Solution prevails in the zone of oxidation. The phenomena of solution are of supreme importance in the concentration of metallic ores. A magmatic ore owes its segregation to a relative insolubility in the magma. A

residual or detrital ore is formed, at least in part, by the removal from a rock of the more soluble constituents, the less soluble thereby becoming concentrated. Sedimentary ores are deposited from solution, either directly or by precipitation, and metalliferous veins represent another aspect of the same processes. "The original magmatic rocks are separated, by solution or leaching, into different fractions; and then—by direct deposition, by precipitative reactions, or by metasomatic replacement—orebodies, and especially vein-fillings, are formed. In most cases probably the final workable deposit is the outcome of a series of concentrations, the result of several inter-dependent processes. By differences of solubility, the constituents of the earth's crust are separated from one another, to be laid down again under different conditions and in different places."*

The greater the number of openings, the greater the possibilities of enrichment. Many small openings are more favorable than large faults for wide-spread oxidation. Friction is greater in capillary tubes than in wide openings; hence the percolation of water is slower, contact with mineral and gangue is longer, solution more complete, and enrichment enhanced. Such conditions favor a thorough leaching of a comparatively shallow zone. It is in the intensely faulted areas that oxidation extends to great depths.

A welded bar of steel is weakest at the weld, so too in the earth's crust, a fracture once formed, even though later filled by vein-matter, is necessarily weak, so that slight movement of the crust may bring about re-opening of fissures, sympathetic breaks, and brecciation. Re-opening of fractures is common. Its effect is far reaching and to it one must attribute many of the big ore bodies. It explains the alternating appearance of oxides and sulphides in the vertical range of lodes; it accounts for irregular oxidation, because clays will be formed by the grinding of the wall-rock and will obstruct the movement of aerated waters. Shear-zones, or areas of brecciation, are favorable places for enriched ore.

It is advisable to study all these structural details, the bedding-planes of sediments, joint-planes of intrusives, cleavages, slips, fractures, faults, and determine, if possible, the dominant lines of weakness. The trend of an orebody will be indicated and the possibilities for ore-shoots suggested.

In his work for the Geological Survey at Bingham, J. M. Boutwell recognized the importance of studying the complex system of fracturing there developed. He plotted patiently the strike and dip, noted all conditions, favorable or otherwise, and soon brought light from the apparent chaos. He found that the fissures devoid of mineral contents trend toward all points of the compass in about equal numbers. The fissures with feeble mineralization trend north-east. Over 84% of those that carry pay-ore range between N 5° and 43° E. In brief, the barren fissures display no regularity of direction, while the mineralized fractures are all included within a small arc of the magnetic circle (see Fig. 13). Other districts have been studied similarly. The complex system of faults and fractures at Butte, Montana, has favored the formation of extensive high-grade orebodies; it has complicated the search for these orebodies; it has given the economic geologist an interesting field for scientific research; it was the cradle of the theory of secondary enrichment as advanced by Winchell, Weed, and Emmons; it has enriched the lawyers who have endeavored to elucidate the effects of faulting in apex litigation.

The surface does not always show the complicated structure, or the relative importance of the different series of fractures. At Bingham "only a comparatively small portion of the several hundred fissures observed underground are recognizable at the surface." The bedding-planes of the sedimentaries, the joint-planes of intrusives, if they are not too highly altered, may be noted; the relationship of dikes or sills to either of these can be established; the influence of major or even minor faults can be detected, so that there is much to be learned even from meagre surface evidence. Again, shearing will be recognized readily. Parallelism of fractures closely spaced will suggest sympathetic breaks, a slow and continued adjustment of the rock massif, from which we may infer that free circulation of oxidizing waters has taken place. Brecciation, with or without subsequent silicification, is a favorable sign. The presence of clay on fault-planes may form an impervious layer to divert the waters one way or another. At the Mount Lyell mine, in Tasmania, a gossan ore-shoot followed the foot-wall of the lode; no copper was found on the upper side, but a remarkable series of rich lenses of silver and copper was mined from the under side.

In the life-history of an ore deposit, that of the outcrop is the most eventful. It is subject to ceaseless warfare; it is torn to pieces by violent earth-movements; it is attacked by gases, waters, and acids; it is drenched by rain, frozen in winter, scorched in summer; the sand-laden winds burnish it; the soils try to protect it. Is it any wonder that the metal contents seek refuge at a lower horizon? They gather themselves in zonal array, temporarily protected by the impoverished surface, to await the constant attack of the elements. These zones are continually descending; it is an orderly retreat under normal conditions, but when the onslaught is too great, much of the metal is dissipated: its form is annihilated, its disorganized remnant is made captive and transported elsewhere.

Ore at the outcrop may represent what was once primary mineral: afterward enriched sulphide ore; still later oxidized, enriched sulphide ore; later still leached, oxidized, enriched sulphide ore: and finally it may have become the gossan. Any one of these particular phases may show at the surface. Again, the transition from one condition to another may be very slow; they may be

*F. W. Clarke, 'Data of Geochemistry,' U. S. G. S., Bulletin 616, p. 633.

serially blended with no sharp line of demarcation. The actual depths of the various zones vary widely in different districts, in different parts of the same district, or even in the same deposit, depending upon the local conditions of the water circulation.

In support of these statements, I shall quote from the writing of three close students of the subject.

FIG. 11. OUTCROP OF VEIN AND DESERT TOPOGRAPHY. PLANET MINE, BOUSE, ARIZONA.

F. L. Ransome says of Bisbee: "Within the transition zone between completely oxidized and unaltered sulphide ores, which has a maximum depth or thickness of about 900 ft., the oxidizing processes are controlled to a large extent by recent, irregular fissuring and by the relative permeability of the various sulphide masses to descending waters. Fissures, cutting through masses of lean pyrite, are almost invariably accompanied by streaks of rich ore, often containing chalcocite together with cuprite and native copper. Where there are several such fissures closely spaced, important orebodies result."

Waldemar Lindgren says of Morenci: "The oxidation does not extend down to any well defined water-level, which must be far below the deepest workings, but acts most irregularly, sometimes leaving fresh, metamorphic limestone at the surface and again reaching down to a depth of 400 ft. along fissures and faults. The present orebodies probably fell an easier prey to oxidation by reason of their richness in sulphides and their favorable exposure to percolating waters."

Reno H. Sales says of Butte: "Examined from the surface downward, the oxidized portion of a copper vein will show but little variation in physical character or mineral composition between the outcrop and the sulphide ore. The line of separation, marking the change from oxidized to sulphide ore is very sharp and clean-cut. There is no partial oxidation of the veins, no mixture of sulphides and oxides. The entire change in any single cross-section takes place within two or three feet vertically. Generally the sulphide ore, through slight changes in the relative abundance of certain minerals, indicates the proximity of the oxides, while in the case of the oxides, there is seldom, if ever, any change to indicate a nearness to sulphides."

It is essential to determine the original position vertically of that part of the orebody exposed today. This done, we can formulate some idea of its further possibilities.

The changes wrought in the zone of oxidation are the net results of the combined work of the elements from above and of subterranean forces. The latter cause the main fractures; they buckle the surface and force into or through the overlying rocks great quantities of molten material, initiating mineralization. Then, on the shrinkage of volume, due to cooling, new planes of weakness and rupture develop, and finally the metallic residuum of the magma escapes, completing the primary mineralization. Now comes the deluge from above, gathering strength in its descent through the belt of weathering, destroying the original character of the mineralization; but its vitality is soon exhausted: wearied of its burden, it deposits secondary sulphides, and finally it is lost in that water zone, the top of which is known as the ground-water level.

Outcrops and the zone of oxidation are so closely related and intimately associated that they must be described and discussed together. Forces that have developed the one have influenced the other, and as ground-water level has been the accepted dividing line between

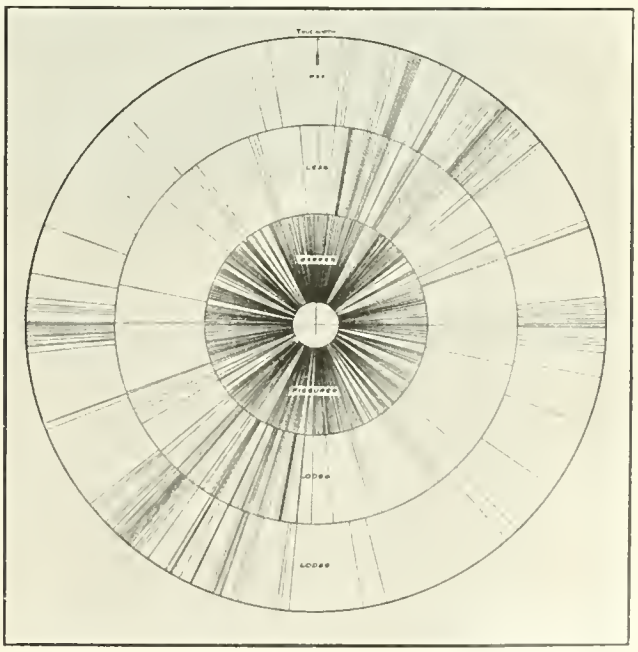

FIG. 13. DIAGRAM SHOWING TRENDS OF BARREN FISSURES AND OF LEAN AND PAY VEINS AND LODES OBSERVED IN BINGHAM, UTAH. (Copied from Prof. Paper No. 38, U. S. G. S.)

the indicated and the indicated in the voluminous discussion of secondary sulphides. I shall limit myself to that portion of copper deposits directly influenced by meteoric agency.

All the waters in the belt of weathering are of meteoric or surface origin. They are the most potent factors in the enrichment of primary deposits. Generally speaking, their power is spent on reaching the ground water level, although in a number of cases they have enriched areas below this level by diffusion of contents.

Ground water level is the level at which water lies in any particular district. It tends to follow the contour of the country. If the rock is shattered and the openings are large and numerous, the ground-water level will be at a considerable distance from the surface, since meteoric waters can readily penetrate. There is likely to be a marked rise in the level where the openings change from super-capillary to capillary size. The proximity of streams or other bodies of water cause the ground-water to rise. In the eastern United States, the depth of ground-water varies from 0 to 100 ft.; in the high limestone region of Kentucky, it stands about 220 ft. below the surface; in the western part of the great Plateau region east of the Cordilleras, it is reached at from 150 to 240 ft., whereas, in arid regions of the Southwest, it may be 1000 ft. or more down. The average depth throughout the United States is from 90 to 150 feet.

Franz Posepny first called attention to the striking difference of conditions above and below ground-water level. James F. Kemp vigorously attacked the theories advanced by C. R. Van Hise regarding the relative work of meteoric and magmatic waters in the origin of ore deposits. He pointed out that there is a grave objection to the supposition of a universal ground-water level. The deep shafts of Lake Superior are dry, even dusty, although from their geologic structure and proximity to large bodies of water, conditions are favorable for much water. At Pzribram the mines are dry at 2400 feet.

Whenever possible, it is advisable to determine the permanent water-level in the district being examined, as it may have a marked bearing on the value of the property, but in interpreting the phenomena of the outcrop, it is well to bear in mind the later geological history of the section, because subsidence, together with choking and elevation of surface drainage, may raise the ground-water above its old level. Where the rainfall is slight, contributions to persistent water are proportionately small; the level may be far down, or, if the rocks are shattered, it may be entirely lacking, and oxidized ores, so far as they can be produced without the aid of much water, may extend to depths infinitely great.

I use the term water zone advisedly. T. A. Rickard has, on several occasions, emphasized the importance of recognizing a stratum in the earth's crust above and below which water, as such, is not found. The lower limit of ground-water may present a very irregular surface, depending on the penetration of fractures. In the *Engineering & Mining Journal* of March 14, 1903, and in the Mining and Scientific Press of June 27, 1908, Rickard cites several instances to support this contention, and says, "All the evidence is in favor of the essentially superficial character of ore formation; in other words, the precipitation of ore, and especially the concentration that makes the richer bodies of it, is measurable from the surface accessible today and has been affected by geological conditions near that surface. Of these conditions the most important is the existence of a blanket of meteoric water charged with oxygen and salts leached from the oxidized zone overhead."* This is an important subject and invites investigation and discussion.

Ground-water level is never the same over any long period of geologic time. It is constantly changing, and this movement in the vertical scale has an important bearing on the mineral sequence, causing alternating periods of oxidation and reduction, enrichment and impoverishment. Practically all the workable deposits of today are the result of successive concentrations, effected by circulating waters. The periodic rise and fall of ground-water is most marked in arid regions. These fluctuations cause the oxidized and enriched areas to exhibit great irregularity in vertical range.

At Kyshtim, in Siberia, the level of ground-water is relatively constant, 100 ft. below the surface of the broad shallow valleys in which the copper deposits are found. There is a noted parallelism of the several mineralogic zones with the ground-water level. The latter has an intimate relation to the vertical range of minerals. The gossan does not extend down to the water, indicating the retreat of standing water to greater depth. The zone of oxidation is only about two-thirds the width of the primary ore. Leaching and impoverishment of copper contents extends down 50 to 135 ft. below ground-water, while residual sulphides are found 25 to 95 ft. below the present level, again attesting to the variability of the horizon of ground-water.

At Ajo, Arizona, the oxidized ores continue to a horizontal plane 20 to 150 ft. underground. This plane does not conform to the present topography but corresponds with the present water-level.

John A. Reid describes† an interesting situation at Copperopolis, in California, where the surface zone of oxidation is very shallow, 30 ft. or less, and the zone of enrichment entirely lacking. He attributes this fact to the intense lateral pressure in the rocks, preventing the formation of an active vadose circulation.

Ground-water level oscillates in different localities with seasonal changes, and has been subject to rise and fall in geologic time, but generally speaking, it moves downward with the erosion of the surface. We must not be misled by this statement, however, for present-day outcrops may be the net result of reactions, chemical and physical, extending over geological epochs.

The zonal arrangement of the products of alteration is influenced by the structure of the rock-mass. They

*M. & S. P., Vol. 96, p. 875.

†*Economic Geology*, Vol. 2, pp. 380-417.

are not constant; any one zone may be highly developed or conspicuously absent, depending on local conditions. At Ducktown, in Tennessee, the gossan extends from the surface to 100 ft. It is rich in iron and has been smelted for a number of years as an iron ore. Below this is a dark-colored area of enriched sulphides, which is approximately parallel with ground-water and present surface, but where the lodes are crossed by running streams, chalcocite is seen at the surface.

As a rule these zones are roughly conformable with the present topographic surface and hydrostatic level, but they may be much more irregular than either. The zone of sulphide enrichment nearly always contains nuclear masses of primary ore. In moist countries the zone of secondary sulphide is usually below water-level, whereas in arid regions it is partly or entirely above it.

Ground-water is generally accepted as the level at which reduction of the oxygenated water begins and where secondary enrichment may be expected. The statement does not always apply, for, if the deposit is very porous, oxy-sulphates may develop and continue for a considerable distance. A mineral soluble under given conditions does not precipitate readily as long as those conditions last. The waters below the persistent water-level are not oxygenated except by diffusion and that only to a limited degree.

Many deposits of secondary sulphide in the arid South-west are above the ground-water level. In a number of mines, the primary ore has been exposed and no water is found. This is probably on account of change of climatic conditions. If the change was sudden, the primary ores may have had but little chance for alteration. Nearly all the mines are dry at Morenci (Arizona) in and below the chalcocite ore. Of these mines, Mr. Lindgren says: "Chalcocite perhaps forms at the present time in the upper levels of the belt occupied by this mineral, where copper sulphate solutions from oxidizing chalcocite above are abundant, and free oxygen absent. Direct oxidation has, in fact, already penetrated to the deepest levels attained in the pyritic zone, due to the presence of fissures and seams, but it is slowly spreading." He regards the chalcocite zone as formed about an ancient water-level much higher than the present. During the period of formation of the Gila conglomerate, the water-level was surely at least several hundred feet higher than it is now, and it was probably still higher during Tertiary time, during which a moist climate most likely prevailed. Precipitation may be caused by evaporation, as is the case in all efflorescenses and incrustations in mine-workings. Melanterite, chalcanthite, goslarite, gypsum, and alum are common in surface workings. Local accumulations of sulphates may lead to the formation of veins of stopeable width, for example, the melanterite veins near Whitehall, in Montana, and the chalcanthite veins of the Bluestone mine, in Nevada, and in Chile. Rapid evaporation may induce surface circulation.

FIG. 12. RAY, ARIZONA. OUTCROP OF OREBODY IN MIDDLE DISTANCE.

The nature of the outcrop will suggest the duration of erosive conditions and extent of their work. Where the mineral contents of a vein are subject to rapid solution, rapid erosion favors rapid concentration. Weathering generally precedes erosion; and where erosion is slow, the surface may be entirely leached of its metallic content, so that large or concentrated areas of enrichment are produced. The present enriched zones not only represent the added value from the known oxidized covering, but may contain that from horizons already eroded.

The estimate of the amount of mineral removed by erosive action is more of academic interest than of commercial value. An exhausted mine is seldom interesting, and that part of an ore deposit which Nature has mined can never be figured as an asset unless it has been concentrated elsewhere on the surface of the earth. Nature is kind to the gold miner in this matter, as is instanced by "The Golden Sands of Nome,"‡ and in all likelihood, the copper deposits of the Red Beds of the Triassic sandstones owe their origin to the re-concentration of transported material.

If we know that the primary ore is uniform in character, the secondary sulphides can be used as a factor to determine roughly the amount of material that has been removed from the present surface. The formula

$$x = \frac{a(l - p) + b(c - p)}{p}$$

x = vertical distance in feet of the eroded portion.
a = present depth of impoverished leached surface zone.
b = depth of enriched zone above accepted datum line of primary ore.
l = assay of the leached zone.
c = assay of the enriched ore.
p = assay of primary ore.

gives but a rude approximation of the amount of material eroded, but in conjunction with other geologic data, can be used to check conclusions regarding the past history of the vein.

It has been applied at Ducktown and shows that there the copper content of the eroded area was dissipated, for the depth of the leached zone now exposed is sufficient to account for all the re-concentrated copper of the secondary sulphide ore.

In the early days of activity in the Ray district, J. E. Spurr determined the amount of schist that has been leached and partly removed, to produce the known orebody. Using the data from nine representative drill-holes, he estimated that 467 ft. of rock had been leached and removed by erosion from the present surface. This agreed with the aerial geology.

The forces at work and the conditions under which they operate in the upper zone are so complex and interrelated that they almost defy analysis or division for individual consideration. Cause and effect are confused. Reactions are reversible and variable chemical conditions cause complementary changes. Oxidation and desulphidation, carbonation and disilication are complementary processes in the oxidized zone. They may take place simultaneously.

The effects of the physical and chemical forces are not independent of one another; on the contrary, they are most intricately interlocked. To a considerable degree any one of the forms of energy may transform into the others; consequently, the action of one almost always produces an effect upon the action of the others. Frequently, all of the forces, contributing to the constant change, are important simultaneous factors in the results; again, one or two of the forces may be prominent or even dominant, the other playing a subordinate part. In every transformation, if all the energy-factors of the entire system be taken into account, some of the energy is converted into heat, and heat accentuates chemical change.

In the study of the underground circulation, one has to consider the total effect, the final result of all the component causes and effects rather than the niceties of simple operations. Circulation is rapid in proportion as the hydrostatic head, the gravity, and mechanical action are great. It is slow in proportion as the internal friction is great. In proportion as the openings are continuous, it will be rapid; in proportion as the porosity of the rock is increased, circulation will be accelerated. Of all these the size of the openings is the most important, and as a corollary, the oxidation of an orebody will be advanced by the development of these favorable conditions. The molecular structure of the vein or deposit will influence percolation; hence, anything that tends toward abstraction of material, chemically or mechanically, will promote leaching and oxidation. For a given pore-space per unit of area, the faults are likely to give a greater flow of oxygenated waters than areas of shearing or fissility. This follows from the greater size of the few openings. Hence, other things being equal, the zone of oxidation in veins is generally more advanced and much deeper than it is in the disseminated deposit. The size of openings also effects the transmission of oxygenated waters, for the smaller the opening the greater the quantity that is held by imbibition or adhesion to the walls. Here the time element comes into play, for the solvent power of water is in proportion to the time of contact. Waters moving slowly are the more potent. The geological—I might say the economic—work of the ground-water is favored by smallness of openings, by time, pressure, and heat. Pressure and temperature are factors of depth and therefore influence the vertical range of the work done by circulating waters. Heat depends upon depth of penetration. It is increased by chemical action, mechanical action, and the presence of intrusive rocks. Not only is the rate of solution increased by higher temperatures, but the capacity for holding material in solution is greatly augmented. The hotter the water, the less the viscosity, which assists flow through minute openings. The underground journey of waters seeping downward may occupy centuries of time. The adjustment of a rock to its environment is never complete; therefore changes are always in progress; and the conditions are always those of chemical dynamics; but the changes are so slow that an attempt to duplicate the reactions in a laboratory would fail utterly. It is a case of chemical statics. Time is an essential factor.

Time is not a force or agent of alteration or chemical change, but alteration is a function of time. A comparatively weak force, chemical or physical, working through a long interval of time, may accomplish an incredible amount of work. We cannot compare condi-

‡Geology Applied to Mining, T. A. Rickard. *The Mining Magazine*, October 1914.

tions in the earth with laboratory work; for instance, in the laboratory, quartz is almost inappreciably soluble in water, whereas it is beyond question that enormous quantities of silica have been dissolved and transported in the earth's crust. The geologist has to think not in hours, days, or even years. The effect of time is recognized in constructive and destructive geology. It is of even greater importance in studying chemical change. In proportion as rocks or ore deposits are old, they are greatly altered; in proportion as they are young, they are less altered.

If the geologist ignores this fact, and reasons in reference to the potency of forces and agents in metamorphism, as a chemist and physicist does in the laboratory in reference to the same forces and agents, he is certain to fall into serious error.

Metal Output of the Central States

A summary of mine production of silver, copper, lead, and zinc in the Central States in 1915,* is as follows:

State	Ore treated Short tons	Silver Fine ounces	Copper Pounds	Lead Short tons	Zinc Short tons	Total value
Arkansas	110,000	.....	.....	63	3,209	$801,754
Illinois	†316,000	3,864	.....	954	5,534	1,464,067
Kansas	709,400	.....	.....	1,212	14,365	3,676,448
Kentucky	‡	.....	.....	251	764	213,066
Michigan	12,334,700	585,933	265,283,378	.....	.....	46,721,659
Missouri	15,573,700	57,756	402,160	210,440	136,300	53,683,420
Oklahoma	891,800	.....	.....	7,306	14,314	4,236,636
Wisconsin	1,934,000	.....	.....	2,322	41,403	10,486,212
Total 1915	31,869,600	647,553	265,685,538	222,548	215,889	$121,283,262
Total 1914	23,734,923	482,983	164,398,821	203,845	168,032	$ 55,171,306

*The following are the average market prices used by the U. S. Geological Survey in figuring values of production of metals for the calendar year 1915: Silver, per fine ounce, $0.507; copper (electrolytic), per pound, $0.175; lead, per pound, $0.047; zinc (spelter), per pound (average sales price), $0.124.

†Includes only ore from north-western Illinois.

‡Tonnage not available.

The productive lead and zinc territory in the Central States naturally falls into seven regions, three of which are not limited to any single State. For statistical purposes the tables showing the production of lead and zinc by States are necessary and are so given. For practical information, however, it seems desirable to compile the production by the natural regions, irrespective of State lines. As stated by J. P. Dunlop, of the Survey, the south-eastern Missouri and central Missouri regions produced about 83% of the lead output of the Central States. The production from central Missouri is small, and it is included with that of south-eastern Missouri for convenience. The Joplin region produced 16% of the lead and 76% of the zinc of the Central States in 1915, and was much the largest producer of zinc in the United States, yielding 36% of the total zinc production from domestic ores, against 38% in 1914. The upper Mississippi Valley region yielded a little more than 1% of the lead and nearly 22% of the zinc produced in the Central States in 1915.

Mine production of lead and zinc in the Central States in 1915, by regions, in short tons:

Region	Concentrates Lead[1]	Concentrates Zinc[2]	Metal Lead	Metal Zinc	Total value of metals
Joplin[3]	45,350	321,695	35,052	164,544	$44,101,800
South-eastern Missouri[4]	278,104	1,104	183,906	372	17,379,420
Upper Mississippi valley[5]	3,854	162,029	2,817	46,937	11,905,174
Northern Arkansas	79	8,531	63	3,209	801,754
Kentucky and southern Illinois	1,011	2,172	710	764	256,212
Arbuckle mountains, Oklahoma	.....	132	.....	63	15,624
Total, 1915	328,398	495,663	222,548	215,889	$74,459,984
Total, 1914	294,124	390,213	203,845	168,032	$33,039,174

[1]Includes both galena and lead carbonate concentrates.

[2]Includes sphalerite, zinc carbonate, and zinc silicate concentrates.

[3]Includes south-western Missouri, south-eastern Kansas, and north-eastern Oklahoma.

[4]Includes a very small production from central Missouri.

[5]Includes Iowa, Wisconsin, and northern Illinois.

Arkansas made a great increase in output, namely, 110,000 tons of concentrates against 20,000 tons in 1914. Other States showed increases, in tons of concentrates:

State	1915	1914
Illinois	316,000	261,300
Kansas	709,400	540,500
Missouri	4,004,900	3,179,830
Oklahoma	891,800	763,920
Wisconsin	1,934,000	1,387,490

International Smelting Company Miami Plant

We are indebted to Mr. L. R. Wallace, resident manager for the International Smelting Co., at Miami, Arizona, for the following details concerning the operation of this highly efficient and successful plant.

Drying Plant Statistics

Composition of Charge	%	Analysis of Charge	%
Concentrates	83.6	Cu	30.97
Crushed ore	0.3	SiO_2	16.02
Converter secondaries	8.3	Al_2O_3	5.83
Pyrite	1.9	Fe	16.65
Limestone	2.9	CaO	1.80
		S	19.57
		Undetermined	9.16

Steam produced at 187 lb. pressure and 210° C., per ton of charge, 1321 pounds.

Ruling temperatures in furnace at bridge, 1540° C., at throat, 1220°, gas after passing boilers, 300° C.

Approximate gas analysis at throat: CO_2, 11.6%; O_2, 2.6%.

Draft at throat in inches of water, 0.25.

Temperature of oil at burners, 99° C.

Pressure of oil, 80 pounds.

Pressure of air used for atomizing, 8 pounds.

Converter Plant

Blast-pressure, 11 pounds.

Air per ton of bullion, 142,000 cubic feet.

Average time for blow, 3 hours 10 minutes.

Average weight of matte per charge, 26 tons.

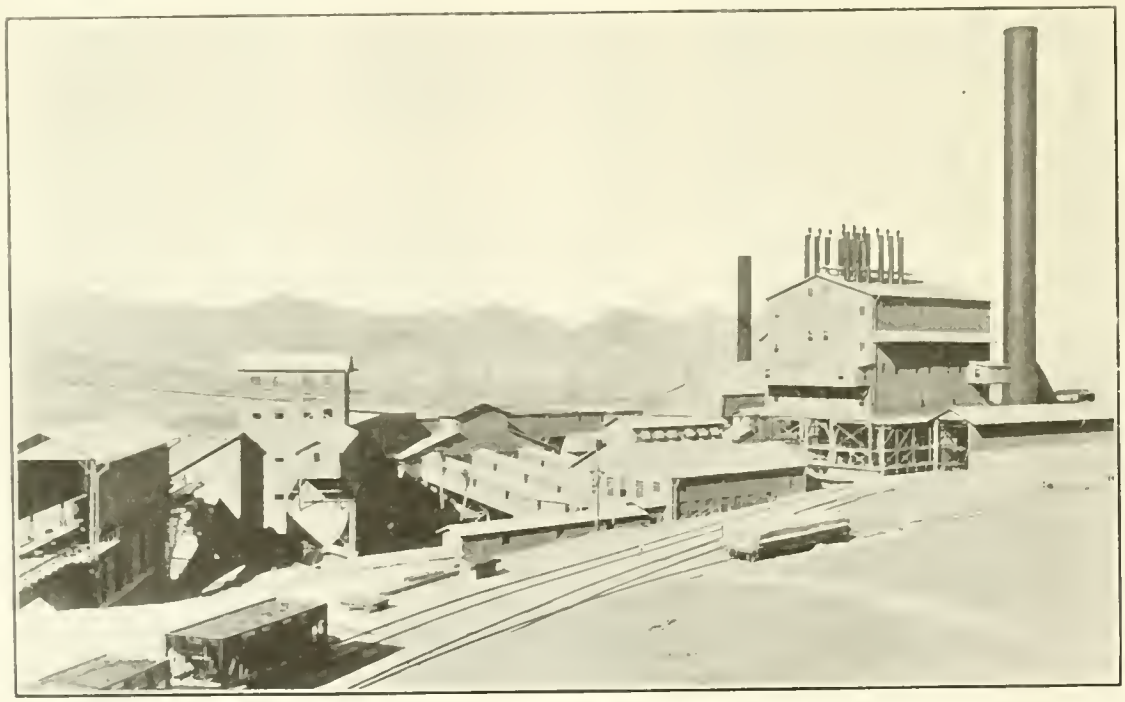
Copper produced per charge, 13.1 tons.

Grade of matte, 51.5%.

Average time to blow one ton of copper, 14.2 minutes.

Tons of ore used per ton of copper, 0.30 ton.

Copper produced per converter-day, 101 tons.



THE INTERNATIONAL SMELTER, AT MIAMI, ARIZONA.

Capacity per furnace-day, 185 tons.

Oil consumed, per ton, 5.15 gallons.

Temperature of calcine, 165° C.

Flue-dust produced 0.7%.

Volume of gas at 80° C., per ton of charge, 43,700 cubic feet.

Maximum velocity of gas in Cottrell tubes, 3 ft. per second.

Average temperature in tubes, 80° C.

Gas contained: CO_2, 4.4%; O_2, 14.4%.

Moisture in concentrate, 15.9%.

Reverberatory Plant

DRAWING No. 22-44.

Tungsten Mining in Arizona

By Charles F. Willis

ARIZONA leads in production of copper, but the excitement caused by the demand for tungsten has given that metal temporary prominence. Tungsten mining is distinctly the prospector's game, the ore occurring generally in small deposits, narrow veins, and pockets. It has been found in Arizona at a number of places.

In the Dragoon district of Cochise county, hübnerite, accompanied by small quantities of scheelite, occurs with fluorite in quartz veins cutting granite, and in placers derived from these veins. This district has produced tungsten ores for years, but many new claims have now been staked. From the mines of the Primos Chemical Co. regular shipments of high-grade concentrate are being made to Pennsylvania. In the Dragoon mountains at Russellville, hübnerite and scheelite are found in small quartz veins, cutting a granite stock, which is in the shape of an oval area four miles by two. Every arroyo in these mountains is being searched for tungsten placers. Many rockers and 'long toms' are in evidence, operated by Mexicans, who get 10c. per pound for the concentrate, and make an average production of 10 lb. per day.

In the Whetstone district in Cochise county, wolframite veins are found in quartz and granite, with a little scheelite. This is about 12 miles south-east of Benson on the west slope of the Whetstone mountains. The American Tungsten Co. has purchased the old Euclid wolframite claims 10 miles south-west of Benson. This company is erecting a concentrating plant, to cost $75,000. The tungsten mines in this district owned by the Primos Chemical Co. are making a good production, 250 men being employed. In the Bower district of Cochise county, in the Chiricahua mountains, scheelite occurs in veins with pyrite and chalcopyrite. Discoveries of tungsten have also been made in Gila county near the Globe-Miami district. The Powers Gulch Development Co. has been organized for the operation of these claims. The tungsten is found to a depth of 120 ft., which is unusually deep for Arizona. West of Miami another strike was made, and upon talk of 60% tungstic trioxide there was almost a stampede to the district. Some of the tungsten shipped from the Powers Gulch claims ran 67%. The property was opened for copper, and nearly 2000 ft. of development work has been done on the 22 claims.

Mohave county has two tungsten districts, the Acquarius, about 12 miles from Owens on the Big Sandy river 60 miles from Kingman, and the Yucca district, 12 miles east of Yucca. At the Tungsten Mountain claims in the Acquarius district the country-rock is chiefly granite, and the ore is in fissure-veins 1 to 3 ft. wide, some of which have been traced for 2000 or 3000 ft. along the strike. Wolframite occurs in bands between quartz, and disseminated in the vein-filling. These bands have a maximum width of two inches of solid wolframite, although there is little regularity; in places the vein-matter is almost barren. What is called the upper system consists of two veins dipping at 45° into the mountain from opposite sides. The wash in many places shows a little tungsten, one 1000-lb. lot of gravel yielding 50 lb. of concentrate. The claims in the

MAP SHOWING THE TUNGSTEN DISTRICTS OF ARIZONA.

Acquarius district have recently changed hands. Last October a 50-ton concentrator was put into operation, and is being worked steadily. In the Yucca district, the Yucca Tungsten Mines Co. is developing its claims preparatory to the installation of a milling-plant. The ore is found in a big dike, and also in a 12-ft. vein parallel with the dike. The Yucca district is important as a producer of the rare metals, including the Leviathan and American Molybdenum companies.

In the White Picacho district of Maricopa county, a vein carrying wolframite has been found; it is only a couple of inches wide, and although of high-grade, it has not been developed. The Pittsburg Tungsten Co. has been operating its copper-tungstate properties at

Cave Creek, 35 miles north of Phoenix, and with success.

The discovery of a 4-inch vein of wolframite has been reported from the Ajo district of Pima county, by M. G. Levy, the owner of the Young American claims. In the Arivaca district of Pima county, locally known as the Las Guigas district, hübnerite, accompanied by wolframite and a little scheelite, occurs in quartz veins. The International Tungsten Co., H. Whitcomb, manager, has produced tungsten ore, and has been incorporated for $10,000,000 to consolidate many of the smaller properties in that district. The Las Guigas Mining Co. was incorporated to take over the Bent and Sampson claims, which are old-time producers of tungsten.

Robert C. Boydkin and associates have a portable mill, which is moved around to various parts of the Las Guigas district. The mill consists of three units, a pumping-plant, crushing-unit, and concentrating-unit; it can be mounted on a wagon for transportation. The concentrator is a 4 by 7-ft. Wilfley table, with special head motion. Fairbanks-Morse engines are used, Roy & Titcomb rolls, and a Blake crusher. The outfit cost about $7000. It has turned out $200 worth of concentrate in a three-hour run.

Scheelite occurs with gold and silver in the Maudina mine in the Old Hat district of Pinal county. Colonel William Cody, better known as 'Buffalo Bill,' has spent a fortune in developing a scheelite property at Bonita in the same district. A mill was erected several years ago, but it was not adapted for economical treatment of the ore, and operations were suspended. With the improved methods of reduction and the higher price for tungsten, it is hoped that the Bonita mine will be revived and that 'Buffalo Bill' will get some of his money back.

Placer operators on a small scale are in evidence in many parts of Santa Cruz county, although in the Calabasas district wolframite is found in place. A low tongue of land between the Santa Cruz river and the Nogales wash is underlain by a porphyritic granodiorite, which is cut by two types of intrusive rocks, one of feldspar and quartz with small amounts of mica, and the other of dense, black, fine-grained dikes, associated with wolframite. The contacts of the dikes with the grano-diorite are well defined, and but little altered except for a fraction of an inch. Along the belt there is contact mineral, epidote and chlorite. The intrusive material is dense and black along this contact and for a fraction of an inch inside is unchanged. The deposits are veins showing a beautiful comb-like structure, and in places there are bands of quartz and wolframite. Sometimes the order of the bands is reversed, and it may be that deposition was simultaneous, as wolframite and quartz crystals are mixed. Post-mineral movement is indicated by the walls, but the veins are not much cut or disturbed. In places the quartz is stuck to the wall by a thin layer of dense greenish material, resembling a silicified shale, which may be the intrusive rock altered by the solutions that formed the vein. The principal gangue-mineral is quartz, but there are small crystals of calcite, and both gangue and walls are iron-stained. The only metallic minerals are wolframite and scheelite. The wolframite is partly crystallized, but most of it is massive. The crystals in large veins have grown into an open space filled with vitreous quartz. The wolframite near the surface is partly altered to iron oxide, showing the form of the original crystal. Most of the veins are less than 10 in. wide, although some are 2 ft., but the wider ones are mostly quartz. The veins traverse the dikes, and the granite near the dikes. The association between the wolframite and the intrusive rocks seems very close. The veins are numerous but most of them are barren; the wolframite being found in small pockets widely scattered. Ore was discovered in 1906 and some shipments are said to have assayed over 50% tungsten.

The Tule Creek, Tip Top, and Eureka districts of Yavapai county have tungsten ores. A custom-mill is planned in the Tule Creek district, to be erected on the creek near Castle Hot Springs. The isolation of this locality, with its lack of wagon-roads, makes a local mill necessary. The claims of the Thompson brothers are being developed, and new locations by R. E. Clark and C. E. Parlan are recorded. One claim is reported to show a streak 10 in. wide of nearly solid wolframite, while another has a streak of equally good quality, but only 8 in. wide. The finding of these claims, five miles south of the Tule Creek mines, indicates that the area is larger than has been supposed. On the Gardner claims a vein 8 ft. wide with wolframite 30 in. wide is being mined. A new strike has been made upon the Cook-Plummer ground in the heart of the district.

Deposits of hübnerite and wolframite are being developed along pegmatite belts in the Eureka and Tip Top districts of Yavapai county. The old Tip Top mine is a producer of tungsten ore; in former years this was a rich silver mine. At that time a large tonnage of what the operators classified as 'black jack' was thrown on the dump; this 'black jack' proves to have been wolframite, and the mine is now being worked to find out how much of this ore was left standing in the drifts and stopes. The first shipment of tungsten ore from Yavapai county was made in April 1914 from the Connors claims in the Eureka district. During the last month, 14 mining locations for tungsten claims in the Tip Top district were filed in two days at the office of the County Recorder. Even the cowboys are deserting the round-up to seek for the metal.

Oatman is now said to be a low-grade district, but the ore is free-milling and some of the veins are as much as 30 ft. wide. The customary procedure of a new company in sinking, say, 400 ft. before cross-cutting to search for ore, costs about $40 per ft., or $20,000 in round numbers, to determine if there is a mine. The United Eastern is estimated to have $10,000,000 in probable ore. As in all gold districts, the question of persistence of ore at depth is engaging the thoughts of the local mining fraternity. Oatman will likely develop into a gold producer of moderate importance.

Mining in Utah

By L. O. Howard

The general improvement in mining conditions noted in my recent articles continues, marked by no one occurrence of great moment, but by numerous small advances in all the districts. Increasing shipments have been noted from time to time from the old districts, but it is only now that the result of the intensive development of the last few months is becoming fully evident. Tintic's production has been breaking records each week, until in the week ending May 19, 242 cars were shipped, bringing the output for four weeks to 43,200 tons, worth over $1,000,000. Not only is production heavy, but all the old-time mines are being re-opened and new incorporations financed. The new chlorination plant is said to have made a slight profit in April. Owing to trouble with the roasters and the high cost of chemicals, neither capacity nor extraction has been brought to the highest point. Effort is now concentrated on increasing the capacity and efficiency of the roasting-plant. Competent labor is scarce in the district and leases are in great demand.

The effect of new development work has also been felt at Bingham, where a new producer has been developed in the Silver Shield. Two veins of $30 to $40 ore, 2000 ft. apart, are reported. The Utah Copper mills are treating an average of 27,000 tons per day, on occasion handling up to 35,000 tons. Favorable indications are noted in the tunnel of the Bingham-Tooele. The Utah-Metals, now earning nearly $200,000 per month, may add a flotation department to its mill, which has a capacity of 225 tons per day. A dividend is expected in July, making the company the second new dividend-payer in the district this year.

At Park City, work has been commenced on the new adit of the Silver King Consolidated, and also on its mill. The shipping list now includes 12 companies. The New Quincy has furnished the latest sensation, the value of its stock having quadrupled in a week, on the report of a 10-ft. face of $30 ore in a bed that was discovered accidentally in the drift from the top of a raise put up from the Daly West 900-ft. level, through which the property is worked. The ground adjoins that of the Daly West and Daly-Judge; it was a large producer in the early days, and from time to time in recent years has made small shipments.

The Dugway district, 50 miles from the railway, the Salt Lake route, in south-western Utah, has a number of promising properties, on which development is being resumed. The long wagon-haul limits the grade of ore that can be handled at a profit. Most of the ground has been under location for years and developed desultorily while awaiting transportation. The high price of the metals has made it possible to ship poorer ore, the value of which in some cases has been increased threefold. In the neighboring Clifton district there is much excitement in tungsten, although there has not yet been time to get the benefit of complete development. From $5000 to $10,000 worth of scheelite is being shipped each week by parcel post.

A second company expects soon to start shipments of zinc ore from Promontory. Ore containing 20 to 30% zinc has been developed for a length of 50 ft. along the vein and to a depth of 125 ft. Over 200 men are at work in this locality.

Five properties are shipping from the old Stockton district, and one mill is operated. Zinc ore makes up most of the shipments, although lead, silver, and gold are also sought.

In the Cottonwoods more of last season's producers are sending out ore. Shipments from Big Cottonwood are heavily curtailed during the construction work on the road. Every week adds to the number of new companies. There is now considerable one-man development under way in the lower geologic horizons, the Cottonwood quartzite and slate series receiving most attention. The South Cardiff has been organized to explore this formation south-west of the Cardiff, and a large group of claims along the divide between Big and Little Cottonwood in this same formation is the basis of another incorporation. On the north-eastern side of the district the Big Cottonwood Consolidated plans development in higher formations than those in which ore is being found in any amount. The principal drainage project, the Alta Tunnel & Transportation, has improved its position by taking over 65 acres adjoining the Prince of Wales, Alta Consolidated, and Emma Copper, all past producers and now actively developed.

For years the large deposits of low-grade oxidized copper ore in the Jurassic-Triassic sandstones of south-eastern Utah have been known. It remained for the present prosperous times to render them productive. These properties are situated about 70 miles from the D. & R. G. railroad, and about 35 miles from Moab, in the same part of the State from which ores of radium, manganese, and zinc have been shipped, these also occurring in similar sandstones. A 300-ton mill is said to be planned by one company in which Jesse Knight and Senator Reed Smoot have a large interest.

The valley lead smelters are now operating at capacity and some fear is expressed by the smaller lead shippers that the market will be closed to them. There is, however, plenty of capacity yet to be utilized in the copper plants. Considerable idle blast-furnace capacity for copper ore is available, and while the tonnage of fine ore has increased, the amount received from the smaller mines of the State bears a small proportion to the increased shipments of lead and silver ore. From time to time there are rumors of the intended establishment of a zinc smelter in the valley but it appears much more probable at this time that any facilities for reducing zinc ores will be provided by the expansion of hydrometallurgical methods.

A rich strike of gold ore is reported from the Goldstrike-Virginia mine in Washington county in the south-western corner of the State.

Roasting and Acid-Making at Braden, Chile

*The plants for this work are at an elevation of 6800 ft. above sea-level. Wilfley table concentrate from the mill, containing 33% sulphur and 16% copper, is fed to a 7-hearth Wedge furnace, having a total roasting-area of 2140 sq. ft. On No. 1 floor the temperature is 380° C.; on No. 7, 630° C. In its passage through the furnace the sulphur is reduced to 3%, while the copper-content is raised to 19.2%.

The sulphur, when burned, forms the dioxide gas (SO_2) that is used in the manufacture of sulphuric acid (H_2SO_4). This gas is drawn from the furnace by a motor-driven fan, the impellers of which are of 6% antimony-lead mixture, through a brick flue to the Glover or hot tower.

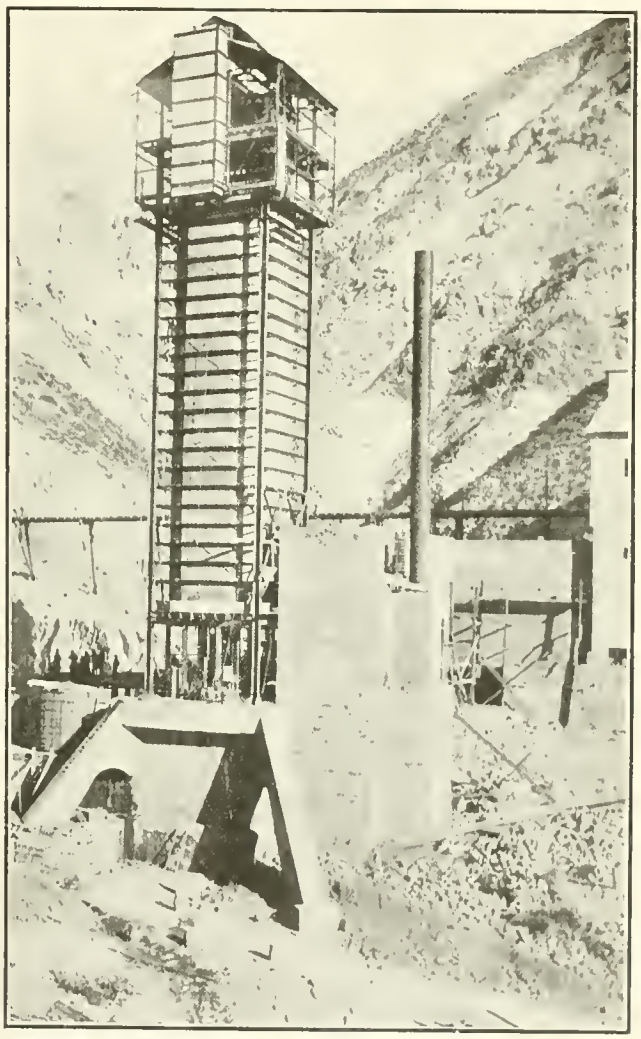
This apparatus is constructed of timber, protected by a tar coating. It is octagonal, 15 ft. diam. and 43 ft. 2 in. high, with sheet-lead curtains hung on the frame within 6 in. of the bottom of a $\frac{3}{8}$-in. thick sheet-lead pan 24 in. deep. The tower is packed with obsidianite, a chemical brick, laid checker or staggered. On top of the brick is 2 ft. of quartz packing for the even distribution of the circulating acid. The top of the tower is of sheet-lead, above which are the system and chamber-acid tanks of 350-cu. ft. capacity each. The most important function of the Glover tower is to deprive the nitrous vitriol flowing from the bottom of the Gay-Lussac tower of its nitrous compounds, and to restore it to a proper state of concentration for application again at the top of that tower. The Glover also cools the furnace-gases before entering the lead chambers.

The Gay-Lussac tower, 21 ft. 9 in. diam. and 68 ft. high, is of steel, with lead curtains, and resembles the Glover. The interior is filled with acid-proof brick arches on which rests quartz packing. The principle of the apparatus is the same as in the Glover, only that in the latter the nitre, absorbed in the acid during its passage through the Gay-Lussac, is de-nitrated in its descent through the Glover, and the nitrous gases from the de-nitrated acid enter the first chamber along with the SO_2 from the furnace, for oxidation and the formation of sulphuric acid.

Three nitre ovens, 3 ft. diam. and 7 ft. 2 in. long, are at the base of the Glover tower. They are charged with Chile saltpetre and sulphuric acid, and heated. The gas generated is piped to the bottom of the Glover tower.

The four lead chambers, in which all the ingredients for making sulphuric acid are mixed, have a total capacity of 187,000 cu. ft. The wooden frame is covered with $\frac{1}{4}$-in. sheet-lead. Water is supplied to the chambers in the form of a spray.

The process of acid manufacture briefly is then: The SO_2 gas from the roasting-furnace, entering the bottom of the Glover tower with the nitrous gas from the ovens, passes up through the brick filling, coming into contact with the descending nitrous vitriol. This vitriol being de-nitrated on its passage down the Glover tower, falls into the lead pan at the bottom, thence to 12 settling-pans. The acid here has a temperature of 100°C., and is cooled before going to the Gay-Lussac tower to recover



THE GAY-LUSSAC TOWER AT BRADEN.

or absorb more nitrogen compounds. The acid gases from the Glover tower pass to the four lead chambers, in which the water-vapor is introduced. Then the gases enter the bottom of the Gay-Lussac tower. A complete circuit is thereby made. The reactions in the lead chambers are

$$2SO_2 + N_2O_3 + O_2 + H_2O = 2SO_2\begin{cases}\text{OH}\\\text{ONO}\end{cases}$$

$$2SO_2\begin{cases}\text{OH}\\\text{ONO}\end{cases} + SO_2 + 2H_2O = 3H_2SO_4 + 2NO$$

The gaseous mixture from the last chamber contains nitrous oxides, which must be recovered to make the plant work properly and efficiently. About 66% of the nitre is saved thereby. Strong sulphuric acid absorbs the fume in the Gay-Lussac tower.

*Abstract from *Teniente Topics*, December 1915.

The chambers yield 23 tons of 66° B. acid daily, while the Glover tower makes another 5 tons. Chamber acid with a specific gravity of 1.58 is either sent to the mill-supply tank for the flotation plant, or to the storage tank at the top of the Glover tower for concentration. The net daily output is from 25 to 28 tons of 66° B. acid.

Acid-eggs or blow-cases are used for circulating liquors to the towers. Compressed air forces the acids out of them through lead pipes to the desired points. 'Duriron' (acid-proof iron) locks are used in the pipe-lines.

Alkalinity of Cyanide Solutions

By Alfred Merritt Smith

This important phase of cyanidation, concerning which so much study and observation has been given by competent metallurgists, is now, as a rule, well understood. A few practical operators of the old school persistently cling to an illusion of benefit to be derived by using, with all ores, solutions of very high alkalinity in lime. In the all-slime treatment of ordinary sulphide gold ores, this must be decried as bad practice. A case came recently under my observation in which excessive lime was the cause of fouling the solution, and increased consumption of chemicals in the mill. Besides augmenting the cost of treatment, the actual extraction of gold was lower than it would have been had less caustic lime been employed in the process.

The ore under treatment was a tough amorphous quartz, verging on quartzite, containing finely-divided free gold, and some pyrite. Traces of copper were present, as shown by the zinc-box reactions, but generally speaking, the ore was clean and simple.

The process in use was all-slime cyanidation. The ore was crushed by stamps, classified, and tube-milled through a closed circuit to the extraordinary degree of 200 mesh, with the exception of 16%, 14% of which passed 100 mesh. This gave a mill-capacity of only 3 tons per 24 hours per 1000-lb. stamp. The average grade of the ore was $15 in gold and one ounce of silver per ton. The discharged residue ranged from $2.65 to $3 gold, and one ounce silver per ton, practically no silver being extracted in the milling. I made sizing-tests on the residue, disclosing the following facts:

Of the total residue, 72% was true slime, or 'colloid,' containing nearly all of the residue-value, the value remaining in the 16% of 100-mesh sand being much less per ton, and negligible. Of the value in the colloid, 55% was dissolved, not washed out, while 45% was undissolved gold; 11% of 200-mesh sand assayed but little more than the 100-mesh sand, and much lower than the colloid.

The loss of dissolved gold was due in part to a poor arrangement of the mill. Insufficient decantation and replacement of gold solution with barren solution caused a high level of solution-value to be reached all over the mill before an equilibrium of values was established. An incomplete precipitation of a relatively small proportion of the total circulating solution that passed the zinc-boxes tended to raise the solution-value still more. The slime going to the vacuum-filter therefore held high gold-value in solution, and the constant loss due to imperfect washing of the filter-cake was thereby greatly increased.

An examination of the mill-solution showed an average strength of 0.55 lb. sodium cyanide per ton, 1.7 lb. lime as CaO, and considerable sulphur as thio-cyanate. Tests made of the solution coming from the tube-mill discharge showed alkaline sulphide present at that stage, probably formed by excessive grinding of pyrite in the highly alkaline solution. Lead acetate and litharge were being added in excess at very irregular intervals, and in almost any quantity, as a corrective to solution trouble, without knowing definitely just what was accomplished by its use other than a belief that it "got rid of the sulphides." On one occasion the operator used so much lead salt in a short interval that the following clean-up was principally metallic lead. Zinc consumption was increased by the lead salt, and, as used, it is doubtful if a real benefit was derived.

At the time of my visit much stress was being laid on the assumed value of high protective lime in the solution, and its use was being carried to extreme lengths on a perfectly normal gold ore. A quantity of slaked lime on hand in a store-room was discarded and thrown over the dump as being worthless, someone having advanced the theory that it had "reverted to carbonate." I sampled this material and found it to be fairly good slaked lime, worth in that locality about $30 per ton.

The following corrective measures were indicated, and are being applied with a marked improvement of results:

1. Coarser grinding. This results in less wear of tube-mill lining consumption, and much greater tonnage milled.

2. A decrease of protective alkali, the mill solution to test from 0.2 to 0.5 lb. CaO per ton. This results in less sulphur in solution, and more rapid solution of gold.

3. An increase of cyanide strength to not less than 1 lb. per ton of solution throughout the mill. Better precipitation results, and any silver dissolved may not be re-precipitated as a sulphide in excessively weak solutions.

4. The regular addition of lead acetate at the tube-mill and the agitators, in small quantities, until reactions at the zinc-boxes show the presence of a little lead, and precipitation of gold and silver in a properly-dressed clean zinc-box is almost complete.

5. Addition of thickeners to the mill were advised to permit wider use of counter-current decantation and replacement, and to permit of all the solution being clarified and precipitated before entering the battery-circuit.

Mining in Nevada

By R. L. Richie

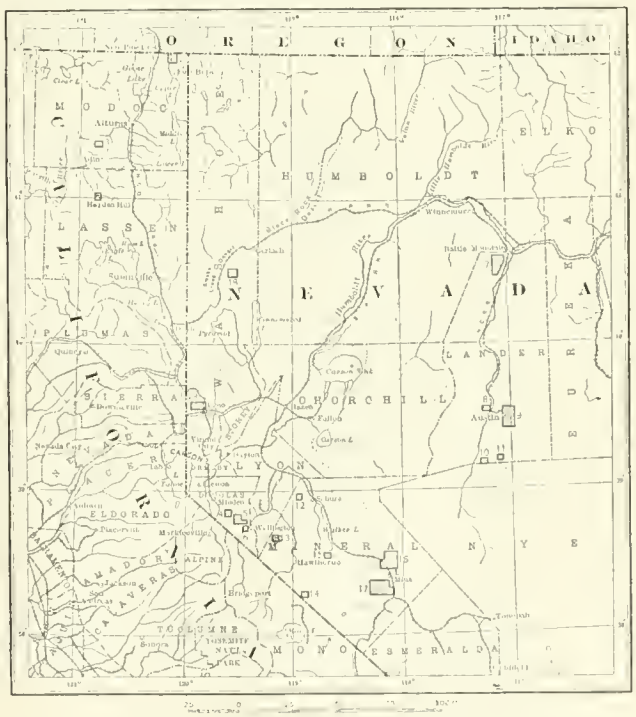
PRONOUNCED activity is seen in every department of mining in Nevada owing to the growing demand for metals other than gold and silver. All parts of the State are enjoying the benefits of this activity, but more particularly are those districts where silver, copper, quicksilver, tungsten, antimony, and zinc are found. Gold mining has not been neglected, profiting from the stimulus that has been communicated to the industry generally, and in large measure from the wider application of the flotation process. Prospectors are to be found everywhere in the hills and the revival appears to have a substantial foundation, happily devoid of the wildcat promotions that have marked earlier periods of mining activity.

Discoveries of tungsten ores have caused veritable stampedes to several localities, notably in the Snake Range region, east of Ely; in the Mina district in Mineral county; at Toy, in Humboldt county, and at points in Esmeralda, Nye, and Eureka counties. Several reduction plants of limited capacity are treating tungsten ores, so that the production of commercial tungsten is attaining notable proportions. For the most part the mineral is found in the form of hübnerite and scheelite. Discoveries of antimony have been reported at a number of points and several of these are being worked.

At Goldfield an addition is being made to the mill of the Goldfield Consolidated Mines company for a 1000-ton flotation plant. The equipment includes 48 Callow pneumatic-flotation cells and accessories. The crushing and re-grinding machinery is already adequate for a larger tonnage than the capacity required for the flotation annex. This new plant will be in operation in June and will involve an expense of approximately $36,000. It should effect a saving of $360,000 to $400,000 annually. A 50-ton test-plant has been operated for several months and has demonstrated the success of straight mill-feed, effecting a recovery of 99% of the copper and 93% of the gold in the ore. The flotation concentrate will be roasted and leached with sulphuric acid, and the copper precipitated on iron, as at present with the cyanidation residue. The oil mixture is composed of 80% coal-tar, 17% creosote, and 3% pine-oil, the total cost of oil not exceeding 8c. per ton.

Work on the deeper levels of the Consolidated mines was suspended early last year, as the high copper content in the deep-level ore precluded its profitable treatment by cyanidation. These levels are again being opened and extended, showing large quantities of gold-copper ore of far better grade than the average treated during recent months, and a product well suited for flotation. Tests with ores from other properties in the district indicate an equal degree of success in treatment, so that it is likely the Consolidated plant will eventually be equipped to treat the output of a number of properties here. Several non-productive mines, upon which considerable development has been done, are being sampled to determine their tonnage possibilities for flotation, with a view to providing facilities to treat this product.

In the Jumbo Extension mine, the product of which is shipped to smelters in Utah, a substantial tonnage of gold-copper ore, too low-grade to ship profitably, has been exposed and is being tested for flotation. Last year the mine produced more than 1,250,000 lb. of copper,



together with some silver, but these metals have been regarded heretofore as by-products. The ore now being shipped contains less gold and more copper and silver. A substantial increase in production will follow the completion of ore-bins at the No. 2 shaft, on the Velvet claim, which hereafter will be the principal outlet of production from the stopes on deeper levels. The Florence Goldfield company has purchased and is enlarging the 150-ton flotation plant erected by a leasing company on the site of the old mill. The dumps, estimated at 50,000 tons of $5 ore, have reverted to the Florence company and blocked ore in the mine is estimated at 70,000 tons that will yield a net revenue, by flotation, of $4 per ton. A Marcy ball-mill has been ordered and will be the principal grinding unit, supplemented by the tube-mill now in use, the estimated capacity being

100 tons. The present flotation equipment, consisting of 11 Janney machines, is said to be ample; another Oliver filter and improved pumping equipment will complete the plant. Ore that is suitable for flotation has been exposed in considerable quantity in the Atlanta, Kewanas, C O D, Black Butte, Silver Pick, Great Bend, and in small quantity in several other properties. Pay ore has been found lately at a depth of 500 ft. in the New Jersey Mines property, three miles east of the central area. Properties now being worked here include the Atlanta, Merger Mines, Kewanas, Sandstorm-Kendall, Florence, Spearhead, Grandma, Great Bend, Yellow Tiger, Black Butte, Silver Pick, Blue Bull, New Jersey Mines, Cracker Jack, and Goldfield Oro. Several others, including Jumbo Junior, will be working shortly. Dividends have been declared lately by Jumbo Extension and Reorganized Booth, both at the rate of 5c. per share.

Tonopah mines are producing a large part of the State's supply of silver and earnings of the producing

companies have been enhanced in important measure by the rise in price of the metal. Mine forces have been increased in nearly all the working properties, while development work is being extended in all directions. A few of the chief producers adopted a policy last year of storing a part of their silver to await better prices and have profited in consequence. Among the foremost producers are the Tonopah-Belmont, Tonopah Extension, Tonopah Mining Co., Jim Butler, West End, Montana-Tonopah, and Rescue-Eula. The last-named has developed lately from a prospect of doubtful value to a mine of substantial proportions. Ore is being treated from several other properties, including the Halifax, North Star, Mizpah Extension, Midway, and MacNamara. Tonopah Extension has lately increased its mill-capacity.

Manhattan, in Nye county, is again attracting interest, owing to the success achieved in the treatment of the refractory ore of the White Caps mine, for which milling facilities will be provided shortly, and to a renewal of activities elsewhere in the district. The Big Four mine and mill have been leased to C. L. Wittenberg of Tonopah, and the mill is being prepared to treat a larger tonnage than before. J. J. McCarthy, a former manager of mines in this district, has secured and is working a property for Oatman mining men. Four mills are in operation in the district and work is progressing on the placers.

North of Rhyolite, the Pioneer Consolidated Mines property has a large tonnage of mill-ore in reserve and the 10-stamp mill is treating 30 tons daily, more than paying expenses. A larger mill, with fine-grinding machines, is to be erected. Near Cuprite, 12 miles south of Goldfield, development is being done by men in the employ of W. A. Clark, directed by E. W. Clark, manager of the Ophir mine in Utah, which is owned by the former senator for Montana. Surface conditions are said to resemble those at the Copper Queen mine, at Bisbee; many locations have been made and are being prospected over a wide area. In the Gold Mountain district, 15 miles south of Goldfield, shipments are being made from the Butte Goldfield property, and ore will be sent by motor-trucks from the Quigley property to a flotation plant at Bonnie Claire. At Hornsilver, 28 miles southwest of Goldfield, high grade silver-gold ore is being shipped from the Dumphy lease on the Orlean property and several others have shipping ore ready. Farther south, the Nevada Empress mine of the Nevada Co-operative Mines Co. has exposed a large vein of good free-milling gold ore. In the Cocomongo district, on the Nevada-California boundary, copper, tungsten, and antimony have been found. In southern Nye county a large deposit of kieselguhr (diatomaceous earth used for dynamite making) has been discovered.

Goodsprings, in Clark county, is making a substantial output of zinc and lead. At Pioche a new mill is nearly completed. Searchlight is producing regularly, but less than in former years.

Ely is now the foremost mining camp in Nevada, in point of population and the value of its output. The pay-roll is said to approach $350,000 monthly. Operations of the Nevada Consolidated Copper Co. are conducted upon an increasingly big scale. Discoveries of scheelite and hübnerite in the Snake Range region, east of Ely and extending for many miles along the west slope of the range, have attracted mining men from all parts of the State.

The Luning district has become one of the chief centres of mining activity owing to the advance in the price of copper. A large number of properties are being developed in a comprehensive manner and ore shipments have reached a large volume. In the Wonder district the Nevada Wonder mine continues to pay regular dividends. Work will be started shortly on adjacent ground, owned by the New York Oro Corporation. Near Mina, Douglas, and Sodaville there have been discoveries of tungsten, copper, and antimony that have caused local excitement.

In the northern part of the State, Humboldt county has witnessed a marked revival of mining activity. Rochester and Seven Troughs are making a substantial production of silver and gold; National is producing some rich ore; a mill is being built at Winnemucca mountain and another will treat ore from Kramer hill, near Goleonda. Battle Mountain, in Lander county, is the centre of several active districts. In Elko county there are good prospects for the revival of Tuscarora, Cornucopia, and other old districts; Jarbidge is producing on a substantial scale and Gold Circle is treating a good tonnage of high-grade ore. Tin has been found near the Isenhood (Eisenhut) ranch, near Battle Mountain.

Mining in Colorado

By George J. Bancroft

The long expected drop in the price of tungsten has finally come. Tungsten is said to have sold as high as $120 per unit ($6 per lb.). It is doubtful if any big lots were bought at this price, but it seems probable that one or two buyers filled their requirements at almost any price, and no doubt a few pounds were sold at or near the above quotation. Large quantities were sold at $75 to $80 per unit. Then the price slumped. Last week the mining papers quoted various prices ranging from $42 per unit upward, but there were few sales made in Colorado. The condition of the market suggests strongly that after a period of feverish buying to fill existing contracts, the purchasers formed some sort of a union and determined not to buy at all until the price was right. However this may be, the 'shake-down' is sure to be a good thing for the tungsten industry, unless the price goes below $25 per unit. Prices have been too high for the last six months. Everybody recognized this fact. Capital does not like to invest in an industry operating under an inflated price. As a result, capital has been shy. While everybody realized that a fall in price was inevitable, few felt competent to name the figure at which the supply and demand for tungsten would find a lasting balance. Now that the break has occurred, it seems fairly certain that a stable price will emerge from the present conflict between sellers and buyers. As soon as this takes place, tungsten mining will command the consideration of capital, and operations can be conducted in a more systematic manner than has been possible recently. It seems the consensus of opinion among well-informed operators that the stable price will not be below $25 per unit and that an important industry can be maintained at that figure. It is earnestly pointed out, however, that there should be a protective tariff established to protect Western miners against possible floods of tungsten from foreign countries.

An important series of tungsten discoveries has been made south of South Boulder creek. From Elk Park, on the slopes of James peak, eastward to Missouri lakes, well out toward the foot-hills, tungsten ore has been developed in important quantities. This district may be considered as a southern extension of the Boulder County tungsten field. Tungsten has been found in the South Park, at Leadville, in Maggie gulch, near Silverton, and in the San Louis valley. It is not known yet whether these new localities will be important producers or not.

Probably the most significant happening in the last month is the announcement that the famous Moffat tunnel has been tentatively financed, providing the present railroad bondholders will consent to exchange their bonds for preferred stock. The Moffat territory has not proved important in metalliferous mining, but it has big resources in its coal and hydrocarbon deposits. As mentioned previously in these articles, the mining of non-metalliferous minerals in Colorado is advancing more rapidly than the mining of the metals. The present output of 'Routt County' coal is important and the tunnel will make it more so. The Moffat tunnel is in a small way somewhat like the Panama Canal in that it provides an improved highway for commerce between important industrial divisions separated by a mountain range. The main continental divide has no good pass; the Denver & Rio Grande climbs over it; the Union Pacific crosses a bleak snow-swept mesa in Wyoming. The Santa Fe and Southern Pacific traverse deserts. The Moffat tunnel will no doubt be connected with the Denver & Rio Grande at Dotsero, and will gain a transcontinental avenue, with advantages over the competing lines.

Extensive drilling for oil is promised for Routt and Moffat counties during the coming summer. Charles A. Smith, consulting engineer for the Wolff Creek Oil Co. of Cleveland, Ohio, already has a rig at work. Incidentally the Midwest Refining Co., which is earning at the rate of $500,000 per month or 40% annum on its outstanding stock of $18,000,000, is now one of the most important oil producers and refiners in the Rocky Mountain states. There will be a good deal of prospecting for oil in Wyoming this summer. Districts that have already been drilled with shallow holes will be drilled deeper. The Laramie plains and the Lander oilfields will receive attention. The Pilot Butte basin seems to be well proved already.

The connection between the Cripple Creek deep drainage adit and the Elkton shaft has been completed, and the shaft re-timbered. Henceforth the waste-rock from the adit will go up the Elkton shaft, saving 4000 ft. of tramming to the El Paso shaft. The water-level in the central part of the Cripple Creek district has begun to subside as a result of the cutting of several water-courses. Cripple Creek is keeping up a steady production of over a million dollars per month. The Vindicator Consolidated Gold Mines Co. paid the last note for the purchase of the Golden Cycle mine 13 months after the purchase was made, and has kept up its regular dividends besides. The total issue of notes was $1,250,000.

The rise in the price of silver has stimulated enterprise in the old silver districts, such as Idaho Springs, Georgetown, Montezuma, Leadville, Creede, Rico, Silverton, Ouray, and Aspen. At Idaho Springs, development is particularly active along the big tunnels. As the snow recedes, work is starting at mines not connected with the big tunnels. At Leadville the principal interest centres around the unwatering projects. Steady progress is being made in all of them. There have been the set-backs customary where electricity is used underground for motive power. Insulators invariably become water-soaked in the course of time and then trouble ensues. After the water-level has been lowered, the drifts must be timbered and cleaned, and development done before a large production can be made. In the meantime, the district is keeping up its usual output from ground already drained. The Little Johnny is one of the wonderful mines of the State. It is now producing copper, as gold, and silver, while tungsten has also been found.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

MINERAL PRODUCTS constitute 90% of Bolivian exports.

GOSSAN is a Cornish word applied to the reddish decomposed rock capping a pyritic lode.

CAPACITY of a mill is generally rated per 24 hours, but in the Joplin district of Missouri the period is only 10 hours.

ELECTRIC HOISTS on the Rand number 143, exclusive of winches. The combined continuous rating of these machines is over 74,000 horse-power.

URANIUM AND NIOBIUM minerals in pegmatite are found in considerable quantity in the centre of the island of Madagascar, off the east coast of Africa.

POWDER CONSUMPTION at the mines of the Mining Corporation of Canada in 1915 amounted to 1.866 lb. per ton of ore extracted, and 11.617 lb. per foot of development.

CYANIDE CONSUMPTION on the Rand may be allocated to the following causes, according to H. A. White: loss by dilution, 30%; loss by cyanicides, 25%; loss as HCN gas, 25%; and loss as NH_3 gas and N compounds, 20%.

GOLD CONCENTRATE containing up to 4% arsenic is being successfully treated at the Boise-Rochester mine, Atlanta, Idaho, by cyaniding with solutions as weak as 0.05% KCN. Stronger solutions attack the base minerals and cause considerable trouble.

SAND-CEMENT is a definite mechanical mixture of portland cement and a silicious material, say 52% and 48% respectively, which, on the addition of water, develops physical properties but little, if any, inferior to those of portland cement when used in mass concrete. The manufacture of it involves no chemical reactions. All that is required is the reduction of the silicious material to a size small enough to permit its being completely mixed with the portland cement. The two materials are then ground together to an impalpable powder, smaller in grain than the portland cement itself.

MISSED HOLES in blasting constitute a danger that it is not always easy to avoid. A miner at one of the Anaconda mines suggests in the *Anode* that a good preventive is to put the primer in the bottom of the hole, instead of at the top of the explosive charge. The 'primer,' it is scarcely necessary to add, is the stick of dynamite that contains the blasting-cap or detonator. He argues, "if a primer is in the bottom of the hole and it misses fire, the fuse or part of it will protrude from the hole in plain view. If the primer explodes, then all the other powder, being on top of it, will explode also. On the other hand, if the primer is placed at the top or centre of the charge, as is usually done, the top of the hole may be blasted away, leaving several sticks of powder in the bottom of the hole." This happening, which is difficult to detect, is not unusual in blasting practice. It may occur where the primer explodes so long after the other holes, that it is in a mass of broken rock when detonation comes. In such cases, the required number of reports would be heard, while still leaving unexploded dynamite in the bottom of the hole.

ZINC ORES do not seem to be confined to any particular horizon. Those of the Appalachian belt are Cambro-Ordovician; at Joplin, Missouri, and Cumberland, England, they are Carboniferous; in Westphalia they lie in the Devonian limestone; while in the Alpine district these ores are most abundant in Triassic limestones. Zinc ores occur in nature in a great variety of ways, namely, (1) as true metalliferous veins; (2) as cavity fillings not of true fissure vein type; (3) as irregular masses in metamorphic rocks; (4) as irregular masses, or disseminations, formed by replacement or impregnations in limestones and quartzites; (5) as contact metamorphic deposits; and (6) in residual clays. The associated minerals are galena, pyrite, marcasite, and chalcopyrite, with calcite, dolomite, barite, and fluorite as gangue-minerals. In the zone of weathering the sulphides are altered to smithsonite, hydro-zincite, and calamine. Although these oxidized ores may contain less metal, they may be of greater value than the unoxidized ores, as they often yield more readily to metallurgical treatment than the sulphide ores.

THE HYDRAULIC RAM is an automatic device by which the fall of a comparatively large volume of water furnishes the power to raise a portion of the water to a height greater than that of the source. Such a system is convenient for furnishing water for drinking or domestic purposes, where, perhaps, a brook can be made to elevate water in a small pipe-line to a dwelling or office. A fall of 3 or 4 ft. suffices to operate a ram; the height to which water will be delivered varies from 10 to 30 times the height of the supply, and the amount of water raised is from 1/15 to 1/4 of the flow. The ram is mechanically the simplest self-contained pumping unit known. The principle of operation is that the water by successive flows, made by its rushing down the drive-pipe, forces a portion of itself into the air-dome and up the delivery-pipe. In construction, a ram has an impact-chamber with two valves, one connecting to the air-dome, the other to the outside air. The former is a check-valve preventing water once in the dome or delivery-pipe from returning. The other valve is the waste-valve, and its length of stroke can be adjusted. Water flowing through the impact-chamber and out the waste-valve soon shuts the latter, and goes into the air-dome, where finally the packed air compels successive rebounds, sending the water along the delivery-pipe.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

PROSPECT MOUNTAIN.—DINERO SILVER.—TUNGSTEN.

The Valley adit, which is being driven into Prospect mountain in charge of Warren F. Page, manager of the Valley and Silver Spoon properties in the Big Evans gulch district, is opening a large area of ground that promises to prove as valuable as any of the rich parts of the district developed in the past. During the last two months, the sinking of an interior shaft has been in progress. A winze is being sunk at a point about 1700 ft. from the portal of the adit, and practically in the centre of an area previously explored by a series of drill-holes driven from the lower workings of the Valley shaft. Rich silver and manganese ore was cut by the drills at an estimated depth of from 150 to 250 ft. below the adit-level. The extent of the orebodies could not be ascertained from the cores, and the winze was immediately started to thoroughly prospect the ground. The winze is now in the contact at a depth of 200 ft. The same formations found in the drill-holes has been reached, and ore is expected to appear in the bottom at any time. The exact value of the ore cut by the drills has not been made public, but Mr. Page has stated that it was much better than he expected. The rapid advance in the prices of silver and manganese will greatly increase the value of the ore, and mining men are eagerly awaiting the announcement of another bonanza brought to light with the cutting of the ore in the winze. Prospect mountain will be the scene of great activity this summer. The finding of commercial orebodies in the Valley adit, a happening certain to occur within the next few weeks, will be the signal for starting work on several large adjoining tracts.

The Dinero property on Sugar Loaf is being blocked out and leased. The decision of changing the policy in operating the property was reached at a meeting of the shareholders held recently. The manager, Warren F. Page, has just completed plans for instituting the leasing system. The Dinero has been one of the richest mines in the district, and has paid many dividends. The property has long been famous as the greatest silver mine in the Leadville district. Ore that has carried as high as 5000 oz. of silver per ton has been shipped, and the average value of the entire tonnage taken from the mine is over $100. Ore in the Dinero and other properties on Sugar Loaf is found in strong fissure veins. Several of these have been cut by the long Dinero adit, and extensive development has been carried on both above and below the level. The property is thoroughly opened, and offers promising opportunities to lessees. Several small parts of the mine now being worked by the company have been retained. The Dinero adit is equipped with first-class electric haulage, and is situated about a mile from the nearest railroad siding. A good road has been constructed to the property, and every convenience has been provided for the transportation of ore. The property is now producing 400 tons a month of high-grade silver ore.

Tungsten exists in the Leadville district. Its presence has been proved by the discoveries of scheelite and hübnerite recently made in the Garbutt and Ibex properties on Breece hill. Bunches of the ore occur in gold vein now being mined in both properties, but as yet no attempt has been made to save it. R. S. Fitch first found the tungsten ore in the Garbutt last fall, when he made a special report on the property. Since that time pockets of the ore averaging 50 to 100 lb. have been found. A peculiar feature connected with tungsten in Garbutt is the greatly increased gold value in the vein immediately surrounding the tungsten and in the tungsten itself. For this reason there has been no sorting of the ore, and the tungsten is shipped along with the gold ore to the smelters, where it is lost in the slag. It has been estimated that $100,000 of tungsten has been wasted in this way. Rich tungsten specimens have been received from prospectors throughout the area between Lake and Chaffee counties, south of Twin Lakes. Several important discoveries of tungsten have been made in this district, and it is thought that large deposits of the ore will be found there during the coming spring and summer. Deep snow prevents prospecting in the mountains until late in May. Reports of the discovery of tungsten in the Homestake district of Eagle county have been received from Red Cliff. This area borders on Lake county on the north-west, and should the reports from across the range prove true, Leadville will no doubt be the source of other discoveries from this side. Mining men are eagerly waiting for the snows to melt so that they can make careful search for tungsten. The Siwatch range to the west is a granite barrier, and offers the most promising field for tungsten.

LEWISTON, MONTANA

BARNES-KING PROPERTIES.—OIL PROSPECTS.

The North Moccasin property of the Barnes-King Development Co. is developed by a shaft 500 ft. deep. The orebody has been followed by winzes 180 ft. below the shaft. The lode varies from a few inches to 50 ft. thick, and in places is 400 ft. wide. It has been followed for over 1000 ft. on the dip. Starting at the surface the orebody pitches about 60°, but flattens out below the 500-ft. level until it becomes almost horizontal. The ore occurs entirely as a replacement in limestone; no porphyry is found in the mine itself. The richest ore, averaging $25 to $30 per ton, is found below the 500-ft. level; this ore is of a soft, clayey character, and so carboniferous that roasting is necessary before cyanidation; even then the recovery is not as high as from the oxidized ores of the upper levels. Pumping is unnecessary above 500 ft., and below that the water is all pumped to a sump at the bottom of the shaft. Not long ago this sump was deepened five feet, when a vug was found. The water now drains naturally away through this crevice in the limestone, saving thousands of dollars annually on pumping bills.

The Kendall mine, near the Barnes-King, has been worked for the last nine months by lessees. During this time they have extracted $40,000 from ore averaging a little less than $4 per ton. The ore has come entirely from the open-cut, and there is said to be more ore opened now than when work was first resumed. The Barnes-King now owns the Kendall property, but the lease has been renewed for another year. The total output of the Kendall has been $3,750,000, from which over $1,500,000 has been paid in dividends.

The Tanberg Oil Co., capitalized at $100,000, has just been organized. J. C. Tanberg, E. C. Tanberg, and B. F. Hoyt of Thermopolis, Wyoming, and H. L. De Kalb and J. E. Lane of Lewistown are directors. Boring for oil has been started by other concerns south of Judith Gap, near Franklyn in Meagher county. Many leases have been obtained in various parts of

Fergus and adjoining counties. Three well defined anticlines are found in eastern Fergus county along the Musselshell river. In certain parts of these anticlines a dome structure is found that would seem to be favorable for oil and gas accumulation. The exposed strata varies in age from the Colorado shale (Cretaceous) to the Lance formation of Tertiary age. Several engineers and oil geologists have recently reported on prospects for oil in Fergus county to both local and Eastern capitalists. Naturally their reports have not been made public.

QUARTZITE, ARIZONA

DRY PLACER MINING METHODS.

At Quartzite, in Yuma county, a large Quinner-Stebbins dry-concentrating plant has been erected to treat the so-called low-grade gravel of this district on an extensive scale. The plant may revolutionize the profitable handling of the large placer deposits of the South-west, where water has always been the principal handicap. In this particular district water is more or less plentiful, both in and about the Quartzite valley (perhaps better known as the Tyson's or the Posas valley) as well as in the Colorado river.

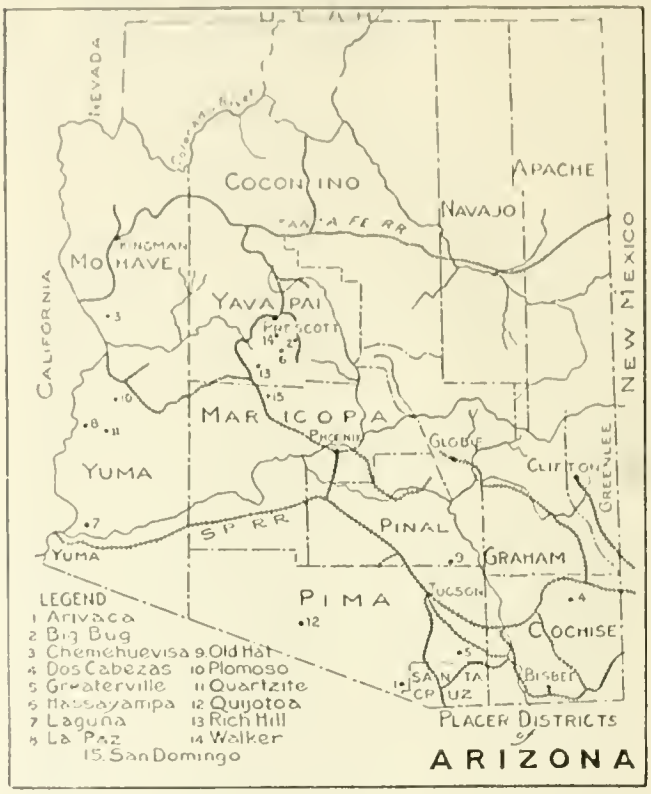
These placers were first discovered about 1865. The town of La Paz was then founded, which later became the seat of Yuma county. In the seventies it supported a population of over 5000 persons, mostly working on placers. It is said that $10,000,000 in placer gold passed through La Paz between 1865 and 1870.

Owing to the gravel being cemented, the gold is in many parts fairly uniformly distributed throughout the deposits, which vary in thickness from a few feet to 80 ft. The minimum value is placed at 50c. per yard, and the maximum much higher. Present conditions and apparatus leave little profit for the miner.

There is nothing new about the Quinner-Stebbins plant, but rather a combination of different parts, all of which have been in successful use elsewhere. The pulverizer is the invention of Max Quinner and consists of a cylindrical drum rolling on large shafting, the latter having numerous steel slugs hung on chains in spiral shape. The shafting revolves at 600 r.p.m., while the drum revolves 400 r.p.m. in an opposite direction. The gravel first passes over a large grizzly on a bin above the machine. Cement gravel fed in at one end is quickly pulverized, the fine product dropping through the drum to a bin beneath, while the boulders are thrown out at the other end with great force, perfectly smooth. A two-inch rim at end of the drum catches all the heavy gold. The fine material is then taken by elevators to a bin above the Stebbins dry concentrator. Waste from both the Quinner and the Stebbins machines is either dragged away or stacked by drag-line or swinging-stacker.

The Stebbins dry concentrator is the invention of Mr. Stebbins of Los Angeles, California. This machine is conceded to be excellent for dry work. When the 'dirt' is perfectly dry it makes a 95% saving, and is especially good for fine gold. (A complete Stebbins plant is in operation on lead-zinc ores at Good Springs, Nevada, replacing a wet plant.) The large tables are 12 ft. long, and work practically on the same principal as the dry placer miner manipulates the gold pan, that is, with a jerky motion. This, with a blower beneath, constitutes the chief working parts. The openings in the table where the air enters consist of small slits, so arranged that the blast from below travels upward and over the table. The gold works along the upper riffles, dropping from one to the other until it drops into a receptacle at the end of the table. The second, which contains much black sand and some fine gold, are carried or the second riffles to the end of the concentrator, and then taken automatically back to the bin to be run again over the table. The Quinner pulverizer has a drying effect on the gravel. The great velocity at which these machines work thoroughly dries even wet gravel.

There are several companies now erecting plants on the Plomosa and La Paz placers. Each has his own method for



transferring gravel to plant, as well as digging and the taking care of the waste material, but all agree that the Quinner-Stebbins combination is the most necessary part of the plant.

The Plomosa and Yuma Consolidated companies are installing 1000 and 2000-yd. plants respectively. The La Paz company will also erect one.

ATOLIA, CALIFORNIA

PRESENT CONDITIONS IN THE TUNGSTEN CENTRE.

The rush of new people continues here, and is now a regular boom. Atolia has fully 1200 inhabitants. New business firms are being organized nearly every week. The town has four general merchandise stores, two stationery stores and newsstands, three butcher-shops, two lumber-yards, three garages, two theatres, three shoemakers, three barber-shops, three pool-halls, a drug store, two physicians, new sampling and reduction plant, a permanent shooting gallery, large bowling alley, blacksmithing and machine-shop, half-a-dozen commodious hotels for the accommodation of transient trade, besides nine boarding houses and restaurants that take care of the regular miners employed in the district: two weekly papers, the *News* and *Tungsten Review*; a bath-house, bakery, three produce dealers, a second-hand furniture store, three ice-cream parlors, and a saw-mill. Besides these Atolia has two systems that distribute water to the people; ample electricity for light, heat, and power, the rate for heat and power being only 4c. per kilowatt; both mail and express *via* Barstow and Kramer over the Santa Fé, and *via* Mojave by auto-stage and truck-lines, that connect with the Southern Pacific twice each 24 hours; about 20 jitneys ply night and day between Atolia and Randsburg and Johannesburg; a stage runs regularly to Bakersfield and Taft, in Kern county, and regular bus-lines to connect with the Owens River Valley railroad at Rand station, about 8 miles west of Randsburg. There are fully 500 dwellings, composed principally of tent-houses and portable

structures that are especially designed for the desert. The people are law-abiding and desire to keep the place decent.

Three or four surveyors are busy in platting and surveying new claims recently located and old ones that have lain dormant for 20 years. The area of tungsten-producing territory now extends 10 or 12 miles east and west and 5 miles north and south. New finds of tungsten are recorded every week, and the production of ore has increased to over 100 tons daily. The price of ore fluctuates, due to local manipulation, and when offers are not attractive, the miners bury their 'spuds,' as the scheelite nuggets are termed, and patiently await a return to better terms. A combine of the buyers lately refused to buy anything, but outsiders soon wired in their orders and there was a rush to acquire what they knew was stored in and around Atolia.

New activities at Atolia have drawn attention to other mineral resources of this belt in San Bernardino county, and there are hundreds of placer and quartz miners that are finding profitable employment in mining for gold, manganese, and antimony. Several important discoveries have been made. The district proper has been a gold-mining region for 25 years, and has regularly produced from $500,000 to $750,000 every year. The Yellow Aster, King Solomon, Windy, Butte, Consolidated, Sunshine, Winnie, Buckboard, Baltic, Napoleon, and Santa Ana, are all mines that have been producing for years.

It is generally considered likely that there will be a return to leasing by the Atolia Mining Co.; those who are in a position to know speak confidently that such is soon to be announced from the head office at San Francisco. Some of the reasons assigned therefor are given as follows: A reduction of expenses in production; better ability to control the sale and price of the product; elimination of all liability in connection with the State law in regard to accident insurance; and the cessation of high-grading, which is now a subject of grave concern. Scheelite, which is regularly stolen in tons from the workings of this company, which has been of such importance to the Atolia district, finds its way through indirect channels to those steel manufacturers who are competing against the plants that derive their tungsten supply from Atolia. Notwithstanding every effort has been made to stop this trouble, there has been but little cessation in the monthly losses of the Atolia company from peculations of both employees and outsiders. It is thought that a change in its employees might solve the problem, and a hundred or more were recently discharged, and this action is pointed out as a direct cause of recent losses disclosed by late arrests and prosecutions of persons 'caught with the goods.'

Outside production, however, goes on apace, and there are individual claims at Atolia that are producing several tons per month, which, in the aggregate, is considerable. All of this goes to Eastern agents, notwithstanding the efforts of local agents to buy it up for those interested in the production by the Atolia Mining Co. Another fact in this connection it is stated is that the Schwab interests, constituting the Crucible Steel Co. of Pittsburg and their auxiliary steel manufacturers, now control the entire product of the Atolia Mining Co., at prices that existed over a year ago, and the recent efforts to depress the market is shown in the refusal of their agents to buy Atolia scheelite. Whatever is correct, outside producers of this district are organizing and already have available several hundred tons that can be bought just now at prices from 75c. to $1.25 per pound for 60% ore. This quantity is increasing every day and, unless taken up by Schwab auxiliary middle-men, must find its way to competitive steel manufacturers, one of whose agents visited Atolia this week.

On May 10, cash amounting to $20,000 was stolen from Illingworth & Dunnell, merchants at Randsburg, who also are interested in mines, grubstake prospectors and lessees, and take care of money for customers generally.

PLATTEVILLE, WISCONSIN

New Producers in the Zinc Region.

The following list includes new power and concentrating plants that have commenced service in the Wisconsin field since January 1, those in course of construction, and others planned and to be built:

Company, Mine, and District	Daily capacity in tons
Milwaukee-Linden, Gilman, Linden	200
Stoner Bros., Stoner, Linden	100
Optimo No. 3, Rolling, Linden	200
Burr, Treganza, Benton	200
Longhenry, Spenseley, Benton	100
Frontier, Hird, Benton	300
Monmouth Zinc, Hammil, Hazel Green	300
Vinegar Hill, Blackstone, New Diggings	300
Oliver Mining Co., Mulcahy, Shullsburg	300
McMillan Zinc Co., Murphy, Hazel Green	400
Little Giant, Little Giant, Shullsburg	100
Coming into service by June 1:	
Blockhouse, Cruson, Platteville	300
Vinegar Hill, Graham, Day Siding	300
Wisconsin Zinc Co., Birkbeck, Mill Brig	300
Standard Metals Co., Anthony, Cuba	200
Sally Mining Co., Sally Waters, New Diggings	200
Building and complete by July 1:	
Wisconsin Zinc Co., Longhorn, New Diggings	400
Wisconsin Zinc Co., Thompson, New Diggings	400
M. & A. Mining Co., Big Tom, Mifflin	300
Saxe Bros., Lampe, Highland	200
Little Corporal, Burke, Galena	200
Plans complete, work of building to start at once:	
Tiffany Mining Syndicate, Lucky Three, Potosi	400
New Jersey Zinc Co., Kennedy, Highland	400
Bell Mining Co., Graham, Platteville	300
Mineral Point Mining Co., Twin Flats, Mineral Point	200

The Kroll and Red Jacket plants are being restored at Highland; Liverpool at Mineral Point; Weigle at Linden; and Merry Widow, White Rose, and Glen Ridge at Galena. Two new zinc-ore 'refineries' have been completed and put in operation within the past 60 days, one at Mineral Point for the New Jersey Zinc Co., the other for the Galena Refinery Co. at Galena, Illinois.

GOLDFIELD, NEVADA

Drilling at the Silver Pick.—Flotation at Bonnie Claire.

Considerable interest has been aroused by the intersection of rich ore in the Silver Pick by the Calyx drill. Drilling was started west of the ore-channel traversing the Goldfield Consolidated, and the shale-latite contact was entered at an approximate depth of 1000 ft. The drill first penetrated a zone of quartz and silicified material, showing some gold, and then passed through shale for 40 ft. Below this was 12 ft. of quartz, succeeded by shale. It is stated both belts of quartz yielded some high assays in gold. Preparations have been made to sink the 700-ft. shaft 300 ft. deeper, and commence lateral work.

Tailing at the Bonnie Claire mill is to be treated by flotation, by the lessees G. W. Quigley, J. Manion, and H. M. Clifford. The Jumbo Extension company formerly treated ore at this plant, and the lease includes its tailing also.

Work has been resumed by the Grandma, Cracker Jack, Jumbo Junior, and other companies. The Yellow Tiger is about to start work, and it is reported the Oro will be operated shortly. Black Butte will probably start shipping on a small scale soon.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Fairbanks

Work on the railroad from the Fairbanks end is to commence from the Sheep station of the Tanana Valley line, then south toward Nenana. Of the 500 men necessary, 300 can be secured at Fairbanks. It is expected that Nenana coal will be available in the interior within two years.

Juneau

April returns of the mines on Douglas island were as under:

Results	Alaska Mexican	Alaska Treadwell	Alaska United
Stamps dropping	120	540	300
Ore crushed, tons	12,880	77,991	42,490
Gold by amalgamation	$10,668	$57,994	$44,222
Concentrate, tons	365	1,780	1,048
Gold by cyanidation	$9,630	$76,257	$40,153
Yield per ton of ore	$1.58	$1.72	$1.98
Operating expenses	$22,185	$97,608	$69,873
Construction	$3,232	$10,462	$6,894
Profit	.....	$24,838	$6,765
Loss	$5,321	.....	.....
Other income	$3,600	$10,801	$3,600

ARIZONA

In Bulletin 20, by P. E. Joseph, the Bureau of Mines at Tucson, has some interesting notes on zinc. The centre of zinc mining in this State is in Mohave county, where are the Golconda and Tennessee mines, which produced a total of 7000 tons of spelter in 1915. In Pima county the San Xavier and Twin Buttes mines produce some ore. In many scattered districts the metal is found, but at present the deposits are of no commercial value. Bulletin 22, by the same author, deals with antimony. In Arizona, stibnite is found in the Vanderbilt mine, Cerbat district of Mohave county. The mineral occurs often in silver in Yavapai county, and with gold in the Bradshaw mountains. Under prevailing conditions none of the antimony deposits of Arizona are of commercial value.

Gila County

(Special Correspondence.)—The Greater Miami Copper Co. has been incorporated with a capital of $1,555,000; par value of stock $1 a share, non-assessable. Directors are William S. Warne, Joseph Perry, N. E. Milford, F. E. Pearl, and C. O. Wentworth, all of Miami. Officers are William S. Warne, president; Joseph Perry, vice-president; N. E. Milford, secretary; and F. E. Pearl, treasurer. The company has taken over a group of 20 claims on Mineral creek in the Globe-Miami district, formerly belonging to W. R. Jones and Grover Sikes. A great deal of work has been done, and several carloads of shipping ore is on the dump. The ore assays 17% copper, 40 oz. silver, and $2.75 gold. A permanent camp has been established, and men are employed in development. The Arizona Corporation Commission has authorized the selling of 25,000 shares at 25c. each, and 25,000 at 50c., the first lot being practically all taken locally. It is the intention of the company to list the stock in New York and Boston early in the fall.

Miami, May 16.

A controlling interest in the Inspiration Needles group of 16 claims and the Prospector group of 32 claims, adjoining the Southwest Live Oak and Inspiration Consolidated properties at Miami, is to be sold by the owners, D. R. Williamson of Globe and others, and C. E. Phillips and others, respectively. Drilling is to commence at an early date.

Yavapai County

This county contains many mines, but more treatment facilities are necessary, and it has been reported by J. E. Russell, an attorney at Prescott, it is likely that a large smelter may be erected near the town.

The Consolidated Arizona Smelting Co. reports as under for the first quarter of 1916:

Blue Bell and De Soto mines produced, tons	25,618
Concentrator treated, tons	19,369
Smelter treated (custom material included), tons	20,842
Copper production, pounds	1,691,000
Silver production, ounces	21,903
Gold production, ounces	905

Net profits were $26,312 in January, $55,771 in February, $78,395 in March, a total of $160,478.

Operations during January and February were seriously interfered with by bad weather, making it impossible to maintain regular shipments.

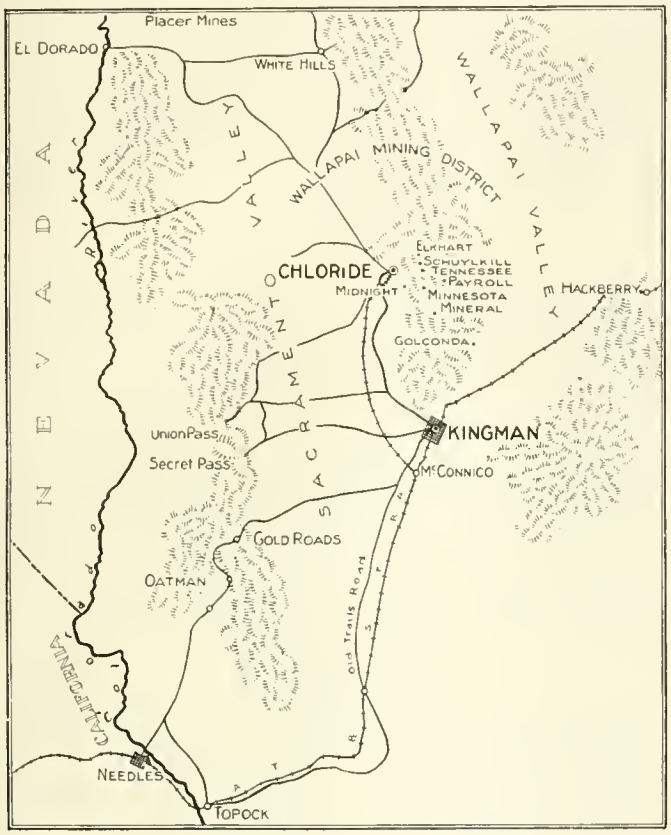
Mohave County

With the Big Jim, United Eastern, and Gold Ore mines developing ore of unusually high value for the Oatman district, with the Carter seemingly just entering its vein on the 350-ft. level, with the Fessenden, Ivanhoe, and United Western expecting to cut their veins at any time on the 500-ft. levels, and with the Boundary Cone driving in its main vein on the new 750-ft. level, optimism in this district is tremendous. In addition to the above developments, the Tom Reed has developed an important orebody on its new 600-ft. level in the Black Eagle workings. More than 100 companies are sinking shafts, their objective points being anywhere from 300 to 600-ft. depth. A number of companies have started lateral work at depths ranging from 300 to 400 ft., but these laterals are as a rule mainly exploratory to enable the operators to keep in close touch with the character of the formation. Building operations continue in Oatman, and machinery is continually arriving. During the last ten days not less than 14 machinery equipments arrived in the district, the hoists ranging from 25 to 40 hp., and the compressors from 300 to 500-cu. ft. capacity. It is estimated that more than 2000 miners are employed at present in the Oatman district, and that more than $25,000 per day is being expended for wages and machinery.

A new gold discovery is reported from the Black Range mountains, 64 miles north-east of Kingman by road, where F. E. Young and C. G. Walker have a rich though small vein.

On May 11 *The Chloride Herald* made its first appearance at the promising centre of Chloride, north of Kingman, on the Santa Fe railroad. In a review of conditions in the district, the editor of the new paper, Anthony McCauley, says that "Chloride has awakened from her 30-year period of coma * * * and again is ready for years of activity." The most important mines near-by are the Golconda and Tennessee—both zinc producers—while the Payroll, Midnight, Schuylkill, Elkhart, Distaff, Molly Gibson, New Jersey, Empire, Keystone, Comanche, Schenectady, and Rainbow are opened to 300 to 600 ft. depth, exposing a large quantity of good gold-silver ore.

Chloride gets its name from the character of the ore found in the district. In the early days millions in silver was extracted in a few years. The ore was taken overland to the Colorado river, floated down to tidewater, and sent by sailing-vessels to Swansea, Wales, for treatment. During this period of the camp's existence the Indian tribes caused the settlers



MAP OF CHLORIDE DISTRICT, ARIZONA.

trouble and several lives were lost. The Chloride Mining Bureau has issued a pamphlet on the Wallapai district, of which Chloride is the main distributing point, briefly describing the principal producers. A list is given of the mines, their depth, and total production. The output in 1915 was $3,000,000; estimates for 1916 place this at $7,000,000.

Yuma County

It is possible that a 200-ton smelter may be erected at Parker by a syndicate represented by A. L. Kreiss, who is now investigating the ore supply.

CALIFORNIA

Oil production of this State in April amounted to 7,372,480 bbl., against 7,525,081 bbl. in March. Stocks declined from 54,436,065 to 53,022,830 bbl. There were 6368 producing wells, while 21 were abandoned, 53 completed drilling, 220 were drilling, and 77 had rigs up. These figures are from the Independent Oil Producers Agency.

Amador County

(Special Correspondence.)—Electric transformers have been installed at the old Eureka mine, and the hoist and compressor are being wired. Three motor-driven sinking pumps will be used to unwater the mine, but until this installation is completed drainage of the shaft will continue by baling. A modern steel head-frame will replace the temporary hoist now in use as soon as practicable. The manager, T. Walter Beam, has a few men engaged in installing pumps and other machinery, erecting buildings, and at other preliminary work. W. Morgan, who has had charge of surface construction work since February, has returned to Colorado, where he is to erect a mill.

Unwatering of the old Rose or Poundstone mine, a mile east of Sutter Creek, continues. The Sutter Creek Mining Co. has an option on the property from L. R. Poundstone, and has a small crew at work re-opening the old shaft near the summit of the hill north of the shaft, through which the last work was done. This mine is equipped with a 10-stamp mill. Alexander Rennie is supervising the work.

Ten stamps of the old Oneida mill have resumed crushing as a result of the ore developed in that property below the level of the drift connecting with the South Eureka mine. The South Eureka company owns both properties, and is contemplating an increase in the number of stamps at the Oneida for the more economical treatment of orebodies east of the main South Eureka workings. H. Malloch is general manager, and W. H. Schmal superintendent of the combined properties. Ninety stamps are in operation, and from 250 to 300 men are employed.

Sutter Creek, May 23.

Kern County

The annual meeting of shareholders of the Yellow Aster Mining & Milling Co. was held at Los Angeles on May 16. The Ancker-Mooers-Burcham faction voted 75% of the stock, and elected the following directors: Albert Ancker, E. D. Mooers, W. J. Cotton, R. L. Burcham, E. L. Kenney, R. A. Dallugga, C. G. A. M. de Pauw. At the meeting of directors, held the next day, the following officers were elected for the year: Albert Ancker, president; E. D. Mooers, vice-president; W. J. Cotton, 2nd vice-president and managing director; and R. L. Burcham, secretary. The 100-stamp mill is crushing 500 tons of ore daily, yielding up to $40,000 per month by amalgamation. Improvements are contemplated at the plant to eliminate waste from the ore.

Nevada County

With a capital of $200,000, the Cassidy Mines Co. has been formed by San Francisco men, with M. Walters as president, to develop the Cassidy and Linden veins, parallel to and between the Empire and W. Y. O. D. at Grass Valley.

Capital has been secured for his Elsie A. mine by Thomas Nolan of the Narrow Gauge railway.

A rich shoot is said to have been cut in the Champion mine.

The Pittsburg mine, about a mile from Nevada City, has been sold by the Weissbein family to the Schlessinger brothers of San Francisco. H. Oates is in charge.

It is proposed to hold a first-aid contest at Nevada City on July 4.

Plumas County

The Walker Copper Co. is being sued by J. C. Gladden for $200,000, alleged to be due under an agreement with J. R. Walker, who, later on, became connected with J. F. Cowan of Salt Lake City in the property.

Shasta County

For the sum of $85,000, and paying delinquent taxes amounting to $13,000, the Stowell mine has been acquired by the Mammoth Copper Co. from Mrs. H. M. Rose of Auburn, acting for the estate of her deceased brother J. H. Stowell, who located the claims.

Redding people have organized the Shasta National Copper Co. to develop property adjoining the Mammoth company.

Sierra County

Owing to the re-opening of a number of mines near Sierra City there is considerable optimism in the district.

Trinity County

The option on the Globe Consolidated mine at Dedrick, held by the Crown Reserve company of Cobalt, Ontario, has been dropped.

COLORADO

Clear Creek County

(Special Correspondence.)—Work is about to be resumed on the Red Oak property. The Sceptre and Sunburst adits will be retimbered and connected by a raise. The Astor mine lying on the apex of the mountain, between the Sceptre and Sunburst will also be overhauled. This mine, famous for the high-grade silver ore in past years, belongs to the Red Oak company. Work will be in charge of Mr. Hershey of Idaho Springs. After the mines are in working order the intention is to re-build the old aerial tramway from the mine to the base of the mountain and there build a concentrating mill on the site of the one burned many years ago.

Frank Ricci has leased the third level of his Mascotte mine, where there is a 4-ft. vein of lead-copper ore, about 1 ft. of which is solid smelting ore of high grade. He has men starting a fourth level, some 150 ft. above the wagon-road. When the orebody is cut, and after tests have been made, he will erect a small mill to treat the lower-grade ore.

Up 120 ft. in No. 3 raise in the Onondaga mines, a 3-ft. orebody has been opened, which is improving as progress is made. On the 180-ft. level the vein is 4 ft. wide. The general manager, Tallmadge Kyner, expects when these shoots have been sufficiently developed that a mill will be needed. Ore is now shipped to the Hudson mill at Idaho Springs at the rate of a carload a day, netting $8 per ton. No sorting is done.

Sampling of the Colorado Central dumps and mine is progressing satisfactorily. Some of the zinc ore in the dumps assays 64.8% metal.

Georgetown, May 13.

Lake County (Leadville)

Drainage projects at Leadville are at the following stage:

The Wolftone pumps are discharging 2100 gal. of water per minute. Good progress is reported at the Harvard shaft on Fryer hill. Water stands at 375 ft., leaving 50 ft. to be unwatered. In 52 days 117 ft. was drained. At the Down Town company's Penrose shaft the water is nearly all out, at a depth of 780 ft. This work occupied 53 weeks. The efficacy of electric centrifugal pumps was thoroughly proved in this work. The old station at 780 ft. is to be cleaned. If the metal markets get weaker, these companies that are to re-open old and explore new ground when unwatering is completed, will suffer considerably, as the projects were started with high prices prevailing.

The First National in Iowa gulch has sent its first lot of lead-silver ore to the Arkansas Valley smelter.——The Ibex also sent 60-oz. gold ore from the Connors lease.

IDAHO

Owyhee County

The old South Mountain property, 20 miles south-west of Silver City, is being financed by Stanly A. Easton of the Bunker Hill & Sullivan company. In its Golconda mine are good shoots of lead-silver ore.

Shoshone County (Coeur d'Alene)

For the first quarter of 1916 the Consolidated Interstate-Callahan Mining Co. reports as follows:

Ore milled, tons (28.15% zinc)	26,514
Lead concentrate shipped, tons (50.4% lead, 19.89 oz. silver)	903
Zinc concentrate shipped, tons (49.12% zinc)	12,972
Crude ore shipped, tons (50.14% zinc)	2,219
Net value of shipments	$1,030,140
Profit	$12,783
Dividends declared for half-year ($3 a share)	1,394,970
The total cost per ton of ore mined was	$7.06

Mill recovery improved from 82 to 88%. The president, John A. Percival, says in his report: "We are gratified to state that the litigation in which the company has been involved during the past year in the State of Idaho has been settled favorably to the company's interests, so that there is now nothing in the way to prevent the early listing of the stock of the company on the Eastern exchanges."

A 150-ton mill is to be built at the Constitution mine in the Pine Creek district. Good lead and zinc veins are being developed.

From its first carload of antimony concentrate the Coeur d'Alene Antimony Mining Co. on Pine creek received $2784 net. The mill is working 10 to 12 hours daily. Twenty men are employed. Electric power will soon be available from the Washington Water Power Co. The company's capital is to be increased. The debt is $35,000.

MICHIGAN

The Copper Country

(Special Correspondence.)—The Mohawk company has purchased from the Roebling interests 900 acres of Torch Lake shoreland, with a mile over to Portage lake. It is a good site for a mill, and gives good dockage on the latter lake.

Ore from the Champion mine is yielding 37 lb. of refined copper per ton. Baltic ore gives 31 lb. The Trimountain mill is being re-built slowly. These are Copper Range properties.

At the Ahmeek mill 8 stamps will soon be ready to crush ore, and the daily quantity is estimated at 5600 tons, next to Calumet & Hecla and Copper Range in output.

At a depth of 1230 ft. the conglomerate has been cut in the New Baltic by drilling. A shaft is to be sunk at once.

Houghton, May 17.

MISSOURI

Jasper County

On the 1000 acres of land recently bought by J. Breigle and others west of Webb City 20,000 ft. of drilling is to be done.

The Cisco Mining Co., leasing land west of Prosperity, has started its 1000-ton mill (per 24 hours). It is thoroughly modern and electrically driven, motors totaling 1200 hp. The jigs are the largest in the district, with cells 48 in. wide and 42 in. deep. The cleaner jigs are 34 by 42 in. Concentrate contains 60% metal. A complete sludge plant has been erected. Ore is mined at a depth of 250 ft., the face being 18 ft. high. The average content is 3% zinc and lead.

During the third week in May the market for zinc-blende sold from $65 to $100 per ton, basis of 60% metal. The output of the Joplin district was 5862 tons blende, 68 tons calamine, and 1078 tons lead, averaging $86, $55, and $95 per ton respectively. The total value was $612,038.

MONTANA

From Madison county on the south to the Little Rockies on the north, and from the Kendall district on the east to Saltese on the west, mining districts of this State are increasing in activity. A dozen centres that were idle two years ago are now as busy as possible.

Beaverhead County

A rush has set in to a gold discovery near Redrock, on the Oregon Short Line, 30 miles south of Dillon.

Broadwater County

Near Radersburg the Keating Gold Mining Co. is to erect a 50-ton stamp-mill. The mine is well developed by a 1200-ft. shaft and adits.——Work is soon to start on the Black Friday mines near-by, recently acquired by Breitung & Co. of New York.

Silverbow County

A cross-cut on No. 22 level of the North Butte mine has passed through a new vein over 4 ft. wide, assaying 10% copper and 8 oz. silver per ton.

On May 22 the Tuolumne Copper Mining Co. closed a deal absorbing the Butte-Main Range, Colusa-Leonard Extension,

and other ground in the producing area of Butte, a total area of over 80 acres, worth $1,000,000. The Main Range has a shaft 716 ft. deep, and is fully equipped.

During April the Butte & Superior mill treated 50,000 tons of ore, yielding 12,080 tons of concentrate worth $83.79 per ton. In April 52,089 tons was treated.

NEVADA

Elko County

Operations in the Gold Circle district are steadily increasing. At the Elko Prince the cyanide plant has produced considerable gold. The mine contains a fair quantity of good gold-silver ore.——Developments are said to be particularly encouraging at the Eastern Star, June Bell, Rex, Esmeralda, and others. Leasing is done to some extent.

Esmeralda County

Final figures of the Goldfield Consolidated company's April operations show the profit to be $60,041 from 30,400 tons of ore treated. Costs were $4.94 per ton. Development covered 2865 ft. at $5 per foot. Nothing of importance is reported from this work.

Humboldt County

On October 31, 1915, the Rochester Mines Co. owed $200,000 for development and mill construction; on May 15, 1916, it was free of debt. With silver at 75c. per oz. the monthly profit is $25,000.

At the La Tosca mine in the Humboldt range, 10 miles south-east of Oreana, the main adit is in 2800 ft., a vertical depth of 1345 ft. A third vein has been cut. John Newman is in charge for the Humboldt Consolidated Mining Co. of Chicago.

Many discoveries of tungsten ore are reported from scattered parts of this county. The Beeson mine, 25 miles south-west of Lovelock, is to have a mill on the edge of Humboldt sink, near the plant at Toy. Teams and a Holt tractor are hauling 500 tons of tungsten ore from the mine for shipment to Utah.

In the year ended April 30, 1916, the Seven Troughs Coalition company's revenue amounted to $337,577, of which $98,978 was clear profit. The 1600-ft. level north drift is opening very rich ore.

Nye County (Tonopah)

In the week ended May 27 the district produced 9400 tons valued at $194,460.

At the Extension the additional 10 stamps have been tested, but the tube-mill, agitators, etc., will not be ready until early in July.

During April the Belmont treated 12,335 tons of ore, yielding 234,727 oz. bullion, and a profit of $103,300.——The Tonopah company treated 7364 tons for a profit of $50,100. Out of 100 stamps an average of 72 was crushing last week.——The Extension milled 7232 tons for 176,819 oz. bullion, and a profit of $89,863.

In the winze below the 1200-ft. level of the Tonopah company's Sand Grass claim the vein is 8 ft. wide, of good grade.

The Umatilla-Tonopah Mining Co. and Montana-Tonopah Mining Co. are to organize a new company to work part of both properties. It is to be called the After All Mines Co.

Storey County

On May 23 fire broke out on the 1400-ft. level of the Yellow Jacket mine, on the Comstock, resulting in four miners dying from fume and injuries. Twelve others were rescued. A fuse blew-out in the motor-driven compressor station, setting fire to the timber.

White Pine County

(Special Correspondence.)—The Nevada Consolidated is crowding production, treating 12,000 tons per day. All but about 1500 tons comes from steam-shovel operations, the balance from the Ruth mine underground work. There is much trouble in holding the ground as it swells, breaking the timbers in a few days. It is understood that the company is to 'glory-hole' from underground certain sections on a level by itself. It is a question, if eventually other methods will not have to be adopted at the Ruth.

On the Consolidated Copper Mines, old Giroux, adjoining the Nevada Consolidated, two drills are in operation, just west and a little south from the Morris. It is reported that a large body of high-grade sulphide ore has been encountered. Shares have risen to $3 from less than $2 each. Rumors are that the litigation has been settled with Colonel Wall and something may be doing later.

There is generally much activity throughout the county, more prospectors in the hills than for many years. While the tungsten areas are attracting the most of them, others are looking for anything in lead or silver. The old Pleadas mine, adjoining the Ward, 18 miles south of Ely, is being put in shape for resumption of work.

It is the intention to start work on the Argus at the old camp of Taylor, across the valley from Ward. This mine had a production in the 80's of $1,000,000 in silver. The adjoining mine, the Monitor, produced about the same. Neither is over 250 ft. vertical depth. A mill is being erected on the Piedmont property in Spring valley, on the east side of the Shell Creek range. Most of properties that have any showing are being worked.

The tungsten boom has subsided somewhat owing to the drop in prices, but most of those interested are confident of profits from the larger milling grade properties.

Ely, May 20.

OKLAHOMA

Tulsa County

At the smelter of the U. S. Zinc Co. at Sands Springs 450 men demanded a 10% rise in wages last week, and struck. The furnaces are now out of commission.

OREGON

Josephine County

The Waldo copper mine has been unwatered and is now being examined. The lower adit has been under way for several months to complete the drainage. At the same time the upper levels yielded some high-grade ore.

UTAH

Juan County

During May the Tintic district produced 46,400 tons of ore valued at $1,125,000. There were 35 shippers.

Salt Lake County

The Clement property of 65 acres, in the centre of the Big Cottonwood district has been acquired by the Alta Tunnel & Transportation Co.

The Utah Metals & Tunnel Co.'s mill is treating 225 tons of ore daily. Monthly profits are over $100,000. A flotation plant may be added. Mine development continues good.

Most of the Alta mines are in better physical condition than ever before. At the South Hecla is 2250 tons of ore, worth $30 to $35 per ton, ready for shipment. Teams are hauling the first ore for the season out of American Fork canyon.

Summit County

At Park City the Daly West mill is again in operation, there being an ample water supply.

During May the district produced 8214 tons of ore worth $350,000. There were 7 regular shippers.

CANADA

British Columbia

To support the Mines Development Act, now before the Legislature, the minister of mines, L. A. Campbell, spoke in its

favor before the House last week. The object of the bill is assistance to prospectors by the supplying of money for the construction of roads, trails, and bridges to facilitate development and operation of claims, the mineral value of which warrants assistance, and to carry out which the sum of $200,000 will be set aside. An investigation of the iron-ore deposits on Vancouver Island is under way, while the establishment of iron and steel works is to be considered.

ONTARIO

(Special Correspondence.)—Part of the Gillies timber limit, embracing about 5000 acres, adjacent to Cobalt, has been thrown open for prospecting and staking. From time to time sections of the limit have been opened for prospectors, and some development done, but hitherto mining operations have met with little success.

The Beaver Consolidated deep shaft is now down nearly 1600 ft. It will shortly be decided whether the policy in sinking to the lower contact between the diabase and Keewatin formations is justified. The monthly rate of sinking is 70 to 75 ft.

Toronto, May 20.

KOREA

The Kapsan Mining Concession, controlled by Messrs. H. H. Collbran, H. R. Bostwick, and associates has been sold to the Kuhara Mining Co., which ranks with the Fujita as the largest copper enterprise in Japan. The concession covers about 600 square miles and includes a developed copper mine 500 ft. deep, together with other prospects. The price was $3,000,000. The Japanese have been nibbling at the property for several years and it is understood that the Government at Tokyo is behind the deal.

MEXICO

HIDALGO

(Special Correspondence.)—Early in May a strike of miners started at Pachuca. They demanded the old rate of wages, paid in silver. The value of the paper *peso* is about 2½ cents U. S., but the Mexican government is to issue new paper, printed in the United States, to replace the present circulation. It was said that the new money would be guaranteed by the Government, making the *peso* worth 10 *centavos Oro Nacional*; but it was later admitted that the value would fluctuate. All railway fares and freight are payable in *Oro Nacional* or its paper equivalent. This resulted in quadrupling the fare from Mexico to the U. S. border. Trains will not be so crowded now, as everybody cannot get 'passes.' Stamp duties have also been doubled 'temporarily.'

Pachuca, May 9.

Later news states that the strike at Pachuca was settled in a few days.

The U. S. Civil Service Commission announces an open competitive examination for metal-mining engineer for the Bureau of Mines, for service in the field, at a salary ranging from $2400 to $4000 per annum. Applications must be filed with the Commission at Washington, D. C., by June 20.

The U. S. Civil Service Commission announces an open competitive examination for mineral technologist in the Bureau of Mines, at $2400 to $3600 per annum. Applications must be filed with the Commission at Washington by June 13.

The San Francisco section of the A. I. M. E. met on May 31. Members of the Am. Soc. C. E. were invited. Slides at Panama were discussed by J. C. Branner of Stanford University.

The ninth annual meeting of the MINE INSPECTORS' INSTITUTE of the United States will convene at Joplin, Missouri, on June 13.

PERSONAL

Note.—The Editor invites members of the profession to send him particulars of their work and appointments. This information is of unquestioned interest to our readers.

ROBERT HAWXHURST is at Philadelphia.

N. H. RUBY of Butters Salvador Mines, Ltd., is here.

R. S. HOLSFORD has returned to Petrograd from the Lena.

HOWARD D. SMITH is examining mines at Alleghany, California.

A. D. MOIR, mining engineer with the Shell Oil Co., is at the Court Hotel.

W. T. BYSETT is re-opening the old silver mines in Socorro mountain, New Mexico.

H. G. OFFICER of New York is on his way to Chile for the Andes Exploration Company.

BENNETT R. BATES, on the staff of H. L. HOLLIS, has been transferred to the Chicago office.

JOHN W. MERCER has gone to Ecuador, on a periodical visit of inspection to the Zaruma mines.

FRED HELLMAN'S departure from New York for South America is postponed until June 10.

EDWARD L. STENGER has returned to Berkeley from the Sissert mine in the Ural Region, Russia.

HENRY B. LOWE and C. C. COMPTON, both from Denver, are inspecting mines at Alleghany, California.

RICHARD A. PARKER has returned to Denver after a month spent in New York, Boston, and Cleveland.

C. B. NICCOLLS, of Chicago, who has been at Lovelock, Nevada, in connection with the tungsten properties, is here.

V. H. SMITH, recently with the Butte & Superior company, is now superintendent for the Beaver Creek Mining Co., at Zortman, Montana.

J. J. MARTIN, general manager of the Chiksan Mining Co., is returning to Korea by the *Empress of Russia*, sailing from Vancouver on June 15.

W. H. SEAGRAVE, formerly manager of the Kennecott mines, is now general manager of all the Kennecott Copper Corporation's mines in Alaska.

J. W. SHERWIN has been appointed general superintendent of the West End and Halifax mines at Tonopah, succeeding the late J. W. CHANDLER.

R. R. LESLIE, manager of Butters Divisadero Co., sailed from New York for London by the *Philadelphia* on May 20, and will return to America in about three weeks.

R. B. WATSON has resigned his position as general manager of the La Rose Consolidated. He is succeeded by G. C. BATEMAN, who has been acting as field engineer for the company, and was previously connected with the Canadian Mining & Exploration Company.

EDWARD W. RAAB, formerly superintendent of the Tennessee mine at Chloride, has been appointed general manager for the Tom Reed Gold Mines Co., in place of S. S. JONES, resigned. CHARLES GRIMES, president of the Tom Reed for about 10 years, has retired, W. B. MOERDYKE, of Pasadena, succeeding him. [Mr. Grimes died since this note was written, on May 29.]

LOUIS BAIRD, formerly at Guadalajara, well known in Mexico for his excellent work as a mining engineer in Jalisco, and recently mill superintendent for the Cinco Minas company, has been killed in action with the British expedition in Mesopotamia, where he was serving as lieutenant in the Royal Field Artillery.

D. M. TOMLINSON, holding the rank of major in the Royal Engineers, has been killed while serving in Flanders. He was general manager for the Kapsan Mining Concession, in Korea.

THE METAL MARKET

METAL PRICES

San Francisco, May 31.

Antimony, cents per pound	37.50
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	7.75— 8.75
Platinum: soft metal, per ounce	$80
Platinum: hard metal, 10% iridium, per ounce	$84
Quicksilver: per flask of 75 lb	$75
Spelter, cents per pound	22
Tin, cents per pound	50
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, May 31.

Antimony: 50% product per unit (1% or 20 lb.)	$1.75
Chrome: 40% and over, f.o.b. cars California, per ton	11.00—15.00
Magnesite: crude, per ton	7.00—10.00
Magnesite: calcined, per ton	25.00—30.00
Tungsten: 60% WO_3, per unit	30.00—40.00

At Boulder, Colorado, the only sales of tungsten ore are by lessees under contract at $50 per unit.

Cobalt averaged $1.50 per pound at Cleveland, Ohio, last year. This is the price of the metal today.

New York, May 25.

Antimony: Dealers quote $2.50 per unit for all positions, a level maintained by high ocean freight rates.

Tungsten: A New York dealer (Charles Hardy) writes: "The market has experienced in the past week a most severe drop. The sudden stopping of all buying by the most important users of tungsten ore has brought about a decline which was accelerated by the fear of speculative holders that the market would break away altogether. Instead of withholding offers for a time, they pressed their offers at reduced prices until ultimately $40, immediate delivery, was reached. At this figure a little buying has taken place and prices now range from $40 to $45 for prompt and forward delivery, but it is still difficult to find buyers. The increased production is discounted by the reduction of prices, and as the demand continues the quotation should remain steady for some time." South American mines are curtailing production on account of drop in prices. As there is continued demand for ferro-tungsten, dealers look for an improved market for ore.

Tin: Arrivals of tin ore are reported at New York, but there is no market, and it is stated that the ore will be stored awaiting demand. Where this market will develop does not appear, inasmuch as the A. S. & R. Co. has covered its requirements for some months to come.

EASTERN METAL MARKET

(By wire from New York.)

May 31.—Re-sale offerings have weakened the copper market; lead is dull; spelter is neglected and weak.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
May 24	71.50	Apr. 18	63.42
" 25	71.50	" 25	65.52
" 26	71.37	May 2	71.45
" 27	71.12	" 9	75.89
" 28 Sunday		" 16	76.40
" 29	70.62	" 23	74.14
" 30 Holiday		" 31	70.81
" 31	68.75

A reaction in silver is still apparent; but the undertone is good, due to continued buying for coinage, a great deal of which has been almost without limit in price. Indian 'bull' speculators rushed in at the top of the market to take profits, and owing to a temporary slackening of coinage demand the market fell. The new regulations in Mexico forbidding export of silver as bullion should eventually benefit the market.

Silver stored by the Tonopah Belmont company at the beginning of March amounted to 980,794 oz. The Tonopah Mining Co. had $431,011 on the same date, calculated at 50c. per ounce.

Eastern Metal Market

New York, May 24.

Without exception the metals are dull, and prices are seeking lower levels. The immediate wants of consumers are covered, some of them have more than they need, and as for the future, they are buying only to cover new orders. Much depends on the placing of additional war orders to infuse activity into the metals, and in this connection it may be noted that the American Locomotive Co. has received an order for fuse parts valued at $9,000,000; but this is the only mention of new orders for shells or their parts.

Efforts to sell re-sale copper, fourth-quarter delivery, at concessions have found no takers.

Zinc has continued to decline, but the producers believe a turn will come soon.

Lead is dull and weak, both as to foreign and domestic demand.

Tin has declined in New York and London, largely because of the liberal supply of Banca tin that is available.

Antimony has slumped badly, consumers showing no interest, even at greatly reduced prices.

Aluminum is unchanged so far as current deliveries are concerned, but 1917 business is reported at substantially lower prices.

With the exception of large export orders for shell and gun forgings, the steel market has experienced less activity in the past week. The mills are turning out material at a record pace, but new business is less impressive. As a rule, prices are unimpaired, although some softness is noticeable in pig-iron, scrap material, and steel billets; but the easiness is due solely to the lull in demand. Any substantial inquiry would quickly revive quotations.

COPPER

The market is extremely dull, and prices are softer, but the situation is a peculiar one. With the producers well sold up to September, there is little reason for them to lower their quotations; but large quantities of electrolytic are coming on the market from other directions. It has been said repeatedly that there was a large amount of unsatisfied demand for the last quarter of the year, but events of the past week do not bear out the assertion. A broker has offered, far and wide, 1,000,000 lb. of copper for the fourth quarter at 28.75c., full terms, but without the slightest success, whereon he made the price 28.50c., full terms, and still failed to obtain results. This metal was bought on speculative account, and it would not be at all surprising if 28c. were accepted for it. There are two sources of copper, aside from the producers, at the present time. There is speculative metal, also a considerable quantity that was purchased by consumers whose plants were tied up for weeks by strikes, yet who continued to receive deliveries of metal on their contracts, giving them more than they can use. The surplus metal they have placed in the hands of brokers for disposal at the best figure possible. The consumers who were approached in connection with the re-sale copper referred to gave various reasons for not buying, among others that they did not wish to buy so far ahead unless it was to cover specific orders, also that they regarded the market as soft, and they thought that they could buy more advantageously later on. In the past week spot electrolytic has been quoted at 29.50 to 30c., June and July at about 29.25c., and August and September at 29c., but it is certain that these prices could be shaded substantially were business to present itself. May electrolytic probably could be had at 29c., and perhaps a fraction less. Lake is nominal at 29c. cash, but none is to be had for near-by delivery. The London market for electrolytic continues unchanged at £158, but standard is down to £136, a spread of £22. Exports from May 1 to 23 totaled 13,496 tons.

ZINC

The slump in zinc has continued, and though the representatives of producers consider that another upward swing is not far off, what they pin their faith on is not evident, unless, as one of them says, "the low prices ought to start something." The galvanizing trade is still working at considerably below normal capacity, and if it sees fit to buy it may be the influence that will change the tide. May spelter is to be had easily at about 14.75c., St. Louis, and 15c., New York. June spelter is quoted at about 14.25c., St. Louis, July at 13.75c., and third quarter at 13.25c. All there is to the entire situation is that buyers are holding aloof from the market. The London quotation for spot is down to £95. Exports from May 1 to 23 totaled 3251 tons. Sheet zinc is unchanged at 21.50c., f.o.b. mill, carload lots.

LEAD

The expectation that the market in lead would be upheld by heavy foreign buying has failed to materialize. Japan had an inquiry out for 10,000 tons, but if the business was closed, it was quietly taken by the leading interest and had but little effect on the market. Domestic consumers are doing nothing. The A. S. & R. Co. continued to quote 7.50c., New York, and 7.42½c., St. Louis, as bases for its average monthly price, but small lots have been sold by independent sellers at less. The general quotation yesterday was 7.45c., New York, and 7.25c., St. Louis, but small lots are known to have been sold at 7.30c., New York. The spot quotation at London yesterday was £31. Exports from May 1 to 23 totaled 832 tons. There is a feeling in the trade that the leading interest will reduce its quotations as soon as it has absorbed any foreign business which may be pending.

TIN

To all outward appearances the market has been quiet in the past few days, but there has, nevertheless, been a moderate amount of trading in future shipments from the Far East. Banca tin is playing a big part in the present situation, inasmuch as it is coming here freely and is being used by many consumers who previously thought they could not do without Straits tin. On May 23 there was a drop of £2 15s. in Straits tin at London, based on the fact that there had been large arrivals of Banca tin at Liverpool. The market here quickly responded to the London decline, and the New York spot quotation dropped from 48.75c., on the 22nd, to 48c. on the next day. Arrivals this month have been good, totaling up to the 23rd, 3102 tons, while there was afloat on that day 3542 tons. One ship which arrived May 17 brought 1100 tons from Batavia, Java.

ANTIMONY

The market for this metal has comparatively gone to pieces. It seems impossible to interest buyers at any price, and the result is that Chinese and Japanese grades have been offered at 28 to 29c., although some of the sellers have discontinued offerings to check the decline so far as possible. May shipment from the East can be had as low as 22c., and some sellers say they doubt if an offer of 25c. for spot would be declined. Needle antimony has been offered at 15c. with no takers.

ALUMINUM

Newcomers having need for aluminum are quoted 58 to 60c. for No. 1 virgin metal, 98 to 99% pure. It is reported that regular consumers of the metal have been covering their 1917 requirements with the leading producer at 35c. for ingots and 40c., for sheets. The spot market is dull.

COMPANY REPORTS

SHANNON COPPER CO.

Owing to the strike and other causes this Arizona company only operated 7 months in 1915. The property is now in full working order. Current assets are $555,688 in excess of liabilities, exclusive of $381,000 Shannon-Arizona Railway Co.'s first-mortgage bonds. The outlook for 1916 is excellent.

The metal output was 6,017,642 lb. of copper, 690 oz. gold, and 35,450 oz. silver, sold for a total of $1,102,275. The profit from this was $248,650. This was reduced to $209,678 through various charges. The balance from 1914 was $703,584, and that for 1916 $834,019.

GOVERNMENT GOLD MINING AREAS (MODDERFONTEIN) CONSOLIDATED

This is one of the newer producers on the Rand, and its equipment is being increased to a capacity of 100,000 tons a month.

The manager, J. L. van Eyssen, reports that in 1915 there was 25,278 ft. of development accomplished. Work on payable 'reef' totaled 9880 ft., averaging $16.80 over a width of 48 in. Large blocks of satisfactory ore were opened. Reserves are estimated at 3,665,000 tons, worth $6.90 across 68 in. The average width of machine stopes was 69 in. There was extracted from the mine 608,546 tons. From all sources 658,387 tons was available, of which 12.529% was discarded as waste.

The mill crushed 576,100 tons, employing 100 stamps and 10 tube-mills. The leaching plant treated 219,785 tons of sand, and the slime plant 353,738 tons. The gold yield was 169,413 oz., and recovery 94.33%.

All costs amounted to $4.70 per ton. The gross profit was £156,210, of which £16,497 was paid the Union Government as profit and income taxes.

IVANHOE GOLD CORPORATION

This is one of the largest gold producers in Australia, operating at Kalgoorlie in the western State. It is now working at a depth of 3514 ft. vertical.

The general manager, R. B. Nicolson, reports that development down to 3470 ft. totaled 4074 ft. From 3320 and 3470 ft. a series of bore-holes were put in to test the east lode after it had left the influence of the porphyry bar. At 3620 ft. more drilling will be done. Ore reserves total 1,026,801 tons, 715,550 tons being in the east lode, averaging $8.84 per ton.

The 100-stamp mill, fine grinding, sand, slime, and concentrate plants treated 238,514 tons for 89,559 oz. gold and 18,489 oz. silver, with 86.75% extraction.

The year's revenue was £389,382, of which £115,984 was profit. Dividends absorbed £105,000, equal to $2.52 per share. On December 31, 1915, cash on hand, etc., was £35,138, and value of investments £174,614. All costs in 1915 were $5.24.

The output to date is £8,241,632 from 3,219,000 tons of ore, and £3,460,000 in dividends.

TAMARACK MINING CO.

The annual report of this company is interesting on account of the remarks of the president, Philip Dexter, pertaining to the proposed purchase of the property by the Calumet & Hecla company. An examination by W. E. Parnall, who knows the ground thoroughly, gave a valuation of $4,616,734, less debts of $349,286, but he does not put a value on the mineral veins, as those that should be worked along with those opened are not blocked out enough. James MacNaughton, general manager, considers that the mine does not pay to operate, except under the present unusual conditions, but Mr. Parnall thinks that another system of mining would make a difference. C. & H. officials state that the unopened lodes are of no value. The C. & H. offers $3,563,486 and to pay the debts, a sum equal to $59 per share on 60,000 shares. The shareholders since voted to sell to the C. & H. at $59 per share.

Results in 1915 were as follows:

Development totaled 880 ft. The five shafts are 3409, 4355, 5253, 4450, and 5308 ft. deep, respectively. No. 1 is used for pumping. No. 2 was extensively repaired, most of the mining was done from No. 3 incline shaft, and No. 5 was used for pumping and mining from April.

	1915	1914	1913
Ore crushed, tons	217,027	57,410	227,563
Refined copper, lb. per ton	17.9	18.7	18.3
Refined copper, pounds	3,888,150	1,074,808	4,168,743
Price of metal, cents per pound	19.10	.....	.....
Cost of metal, cents per pound	17.07	29.08	16.60
Revenue	$742,796	.....	.....
Profit	78,988	.....	.....

The mill was sold for $230,000. The balance of assets at the end of 1914 was $895,993, and at the end of 1915, $1,204,981. No dividends have been paid since July 1907, when the total to that time was $9,420,000. Good progress was made at the re-grinding plant.

TONOPAH BELMONT DEVELOPMENT CO.

This is one of the greatest silver producers in the world, and during the year ended February 29, 1916, returned 2,968,565 oz. In the past 5 years it yielded 1.77% of the world's total output, according to the president, Clyde A. Heller. During the past year the option on the Surf Inlet gold mine on Princess Royal island, British Columbia, was exercised, the final payment of $150,000 being made. A good tonnage of $12 ore has been developed. The Bull Moose mine in Nye county, Nevada, is under option; also the Biddlecome near-by.

The general manager, Frederick Bradshaw, reported that development at Tonopah aggregated 21,362 ft., mostly on the 900, 1000, and 1100-ft. levels. The cost of this work was $1.026 per ton milled, a decrease of 14.1c.; and $6.834 per foot, a reduction of 41.2c. Ore reserves are estimated at 142,164 tons, a considerable shortage. Stoping cost $2.857 per ton. Total mining charges were $4.166 per ton, 14.7c. lower than in 1914-'15.

A. H. Jones, superintendent of mills, stated that the 60-stamp mill and cyanide plant at Tonopah treated 165,157 tons of ore assaying 0.196 oz. gold and 19.603 oz. silver, equal to $13.883 per ton. In the previous term the value was $16.721 per ton. The recovery was 96.18% of the gold and 91.69% of the silver, equal to a total of 92.97%. Stamps averaged 9.15 tons per stamp-day. The cost was $2.682 per ton, or 13c. per oz. of bullion, compared with $2.564 and 10.4c. Increased cost of chemicals and supplies contributed mainly to the higher expense of treatment. A new filter leaf and new type of tube-mill liner was devised, tested, and regularly used. The plant at Millers, 12 miles north, treated 56,730 tons of custom ore, assaying 0.309 oz. gold and 25.01 oz. silver per ton. The recovery was 91.33% of the value, which totaled $1,073,517. The cost was $3.798 per ton. A profit of $33,398 resulted from custom work. Continuous decantation superseded filtration, improving recovery and reducing costs.

Results were as follows:

Gold recovered, ounces	31,112
Silver recovered, ounces	2,968,565
Silver on hand at beginning of year, ounces	1,646,099
Silver sold, ounces (51.76c. per oz.)	3,385,015
Net revenue from metals, custom work, etc.	$1,001,028
Balance from previous year	1,963,286
Total available	$2,964,314
Dividends paid	750,016
Balance for 1916 (after deducting sundries)	$2,084,741

Dividends to April 1, 1916, total $8,018,027.

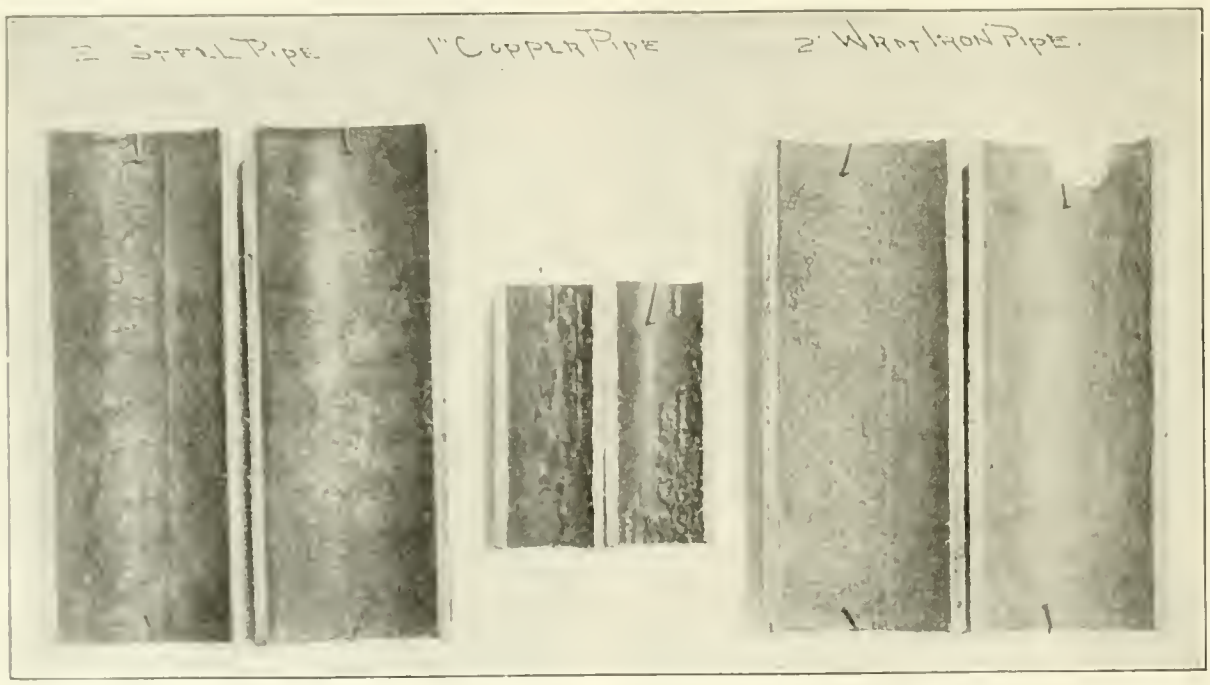
INDUSTRIAL NOTES

Prevention of Corrosion in Pipe

In a 15-page illustrated pamphlet, the reprint of a paper presented by F. N. Speller of Pittsburg at the annual meeting of the American Society of Heating and Ventilating Engineers, is a great deal of interesting matter on the important subject of pipe corrosion.

Casual observation will show marked differences in the degree of corrosion of pipe in service. For instance, hot-water heating-systems and sprinkler-systems show practically no deterioration in service after 25 years, while low-pressure steam returns sometimes give trouble after 15 years' service or less. Galvanized pipe in hot-water supply-systems, where heated by carbonic acid and mineral salts dissolved. Oxygen is also necessary for a continuance of corrosion. The elimination of dissolved oxygen is one remedy to reduce 'pitting' of pipe. An alternative method is to 'satisfy' or fix the free oxygen, using clean iron turnings, or preferably sheet iron, through which the water can flow. The accompanying electrotype shows some 2-in. wrought iron and steel pipe (galvanized) after 13 years use in an 'open' heating system, while the small pipe is of copper, used under the same conditions in a 'closed' heating system for 6 months. The corrosion of low-pressure steam lines depends principally on the amount of oxygen that finds access to the system.

Summarizing very approximately, Mr. Speller considers that in the influence of various factors on corrosion, it appears from the experience gained so far that developments in the metallurgy and manufacture of steel pipe promise to add 50 or perhaps 100% to the life of pipe compared with the service obtained under like conditions 10 or 12 years ago.



CORROSION IN VARIOUS TYPES OF PIPE. (Photo from National Tube Co.)

the water is heated under pressure, lasts from about 5 years upward, depending on the temperature and quality of the water and volume of flow. The last-named condition is so severe on iron and steel pipe that many are compelled to use brass pipe, at a cost approximately 10 times that of galvanized pipe. These few instances are the extremes, but are surely suggestive when it is considered that in pipe carrying ordinary water under some conditions there is no apparent deterioration in a generation; whereas in other cases, the same grade of pipe is seriously damaged in a few years. Some years ago, when steel pipe was comparatively unknown and not fully developed, it was natural to question this material; but comparisons of the modern wrought iron and steel pipe in the same lines in service have shown beyond any question that where corrosion is found, one material suffers on the average as much as the other.

Water alone is not responsible for corrosion, but rather something brought in with the water. All water supplies carry more or less foreign matter in solution. The purest natural supplies are generally saturated with oxygen and carbonic acid, which cause such water to be very corrosive, particularly when heated. Iron is soluble to a certain extent in water. The phenomenon of solution of iron is an electrochemical reaction, which is the initial cause of corrosion, has-

However, it appears well within the bounds of possibility to predict that de-aeration of the water, through the use of plants designed with this end in view, should at moderate expense increase the life of some piping systems four or five times.

Bulletin No. 26 of the National Tube Co. consists of 47 pages deseribing in an informing manner the autogenous welding of 'National' pipe. As oxy-acetylene gas is used so much for welding and cutting now-a-days, every engineer should secure a copy of this useful publication.

The National Tube Co. has also issued Bulletin No. 25, entitled 'National Pipe in Large Buildings.' It covers 87 pages, 44 of which are devoted to photographs of important buildings in the United States, in which the firm's pipe is used. As is usual with the publications of this company, there is a large amount of valuable technical information given on pipe generally.

In Bulletin No. 34-Q the CHICAGO PNEUMATIC TOOL CO. deseriges a few applications of 'Giant' gas and fuel-oil engines, as made by this firm. The illustrations and brief notes tell all that is necessary.

John F. Bertling succeeds R. J. Raley as sales manager for the SULLIVAN MACHINERY CO. in the Lake Superior region, with headquarters at Ishpeming, Michigan.

EDITORIAL

T. A. RICKARD, Editor

EXAMINATION and assaying of ores is not done by the editorial staff of this paper. Our readers are referred to the assayers, metallurgists, and ore-testing works whose names appear in our Professional Directory.

THE Salt Lake Branch of the U. S. Bureau of Mines has contributed much useful information concerning the operation and physics of the flotation process. In this issue we publish a timely article on flotation-oils by Mr. O. C. Ralston, who is known to our readers by his previous valuable contributions to our pages.

DISCUSSION this week starts with a letter on the electric theory of flotation from a highly competent investigator, Mr. James A. Block, of Salt Lake City. Mr. E. Jacobs, a Canadian statistician known to our readers, corrects certain figures of production from the Atlin district in British Columbia. A Nevadan mining engineer throws a hand-grenade at the mining law and urges us to accept the British Columbian rule in regard to locations. Finally, Mr. Leon J. Pepperberg, an experienced geological surveyor gives some useful hints, apropos of the recent article by Mr. Charles A. Porter.

WHETHER mining really benefits from the kiting of shares on local stock-exchanges and the use of mines as an excuse for a game in which the dice are loaded is a moot question. The only good we can see is the actual work done at the mines, the employment given to labor, and the market created for machinery. Wild-cats have been known to develop into domestic felines hardly distinguishable from the best-bred Angoras; that must be conceded. The harm is done not by the open-eyed gambling of the knowing ones, but by the loss of money to that portion of the public unable to distinguish between the 'game' and the 'industry' of mining.

CONTRIBUTORS to this paper are reminded that drawings intended for publication should be made with indian ink, that the lettering should be large enough to permit of reduction, and that the spelling should conform to our style. In making a drawing it is well to keep in mind the amount of reduction that it will undergo when reproduced. Most men who can make excellent sketches or drawings are unable to do the lettering as well as it should be done; to them we suggest the penciling of the lettering, leaving it to our draughtsman to do the rest. Diagrams on sectionalized paper are not suitable; we have to re-draw them because the subordinate lines are too close, even when they are in colored inks that are suitable for photographing. Tracings therefore are preferable. Blue-prints are no good, except to be copied; this entails not only expense but the chance of error. Manuscript should be typed with double spacing to facilitate revision, but we are always glad to have a good article re-typed in our own office. In fact, we do not mind poor drawings and ragged manuscript if they convey useful information clearly, but, like other people, we would like to avoid unnecessary trouble and chances of error. Hence this note.

ABSENTEE ownership in relation to mines is a phrase with a derogatory suggestiveness not always warranted. Many owners of mines, themselves unversed in technology, have sense enough to leave such things to an experienced manager. Mr. Philip Dexter, president of the Tamarack Mining Company, declares that he has never seen the Tamarack mine, and "what is more," he states, "I would not know any more about it if I had." The fussy kind of mine-owner is a handicap to a good superintendent. However, it is well to keep informed. Mr. William Guggenheim is suing his five brothers for $10,000,000, equivalent to a sixth share in a property, the Chuquicamata, that "he did not know was valuable," and that has become even more valuable since, thanks to the combination of clever finance and good management.

ONE of our oldest subscribers writes to say that he is "shocked" at our publication of patents "in the unintelligible language usual to those documents." He suggests that we should translate them into English. We sympathize with him, but disagree as to the remedy. As he admits, a patent specification is a "document," a legal document, the wording of which cannot be altered without impairing its authenticity. Not only would an attempt at transliteration be unwarrantable, but it would be grossly misleading, for the simple reason that the language of a patent is usually intended to be obscure. The editor would be exceeding his function and making trouble all around if he ventured to do anything of the kind. Only this week we heard an inventor complain that certain people, in using his process, were depending upon the description in his patent, which was meant not to disclose the true inwardness of his method, but to afford him protection and to compel them to come to him for engineering advice.

OUR correspondent in the City of Mexico sends a deeply interesting letter, reviewing the conditions of affairs in that country. The reader will find it under Special Correspondence. This letter is written with a frankness that does not mince matters. The impression he gives is that the various factions and their leaders

leave little to choose, even Carranza and his 'liberators' in their scheme to raise money have not hesitated to victimize the peons. Famine has been used as a lever to recruit an army. Our correspondent describes the iniquity of the Casa La Garda, a heartless monopoly to control the grain trade. Then came the paper-money plague, another means of spoliation. The marvel is that mining operations still continue in several important districts, despite the insecurity of life and property and the lack of adequate railway transport. At El Oro the Esperanza and Dos Estrellas resumed operations recently and are still at work, according to the latest advices. At Pachuca there has been a strike among the miners, but the Real del Monte, Santa Gertrudis, and other important mines are active. In the North, of course, the confusion is greater, but even there some of the isolated large mines are pegging away. Whether Carranza is bluffing or whether he really intends to force the United States to withdraw the punitive expedition is a question that will be settled in a few days. The President is unlikely to sanction another veracrusade.

PATENTS are numerous and interesting just now. Much metallurgical ingenuity is at work devising new machines and processes, as our periodical selections indicate. In this issue we give extracts from the Patent Gazette showing that a number of well-known practitioners are among the inventors; notably the great exponent of ore-dressing, Mr. Robert H. Richards, with two devices, one a jig and the other a classifier. Messrs. E. H. Nutter and A. H. Higgins, both of the Minerals Separation company, have patents for treating by-product tars with sulphuric acid, so as to save consumption of acid by direct addition. Mr. A. W. Thompson has another flotation patent, in which a jet of gas is used to break the froth, after it has done its duty. The same result, of de-aerating the froth, can be achieved by dropping the froth on a rotating disc. Mr. Karl Senn, maker of the well-known concentrator, contributes an ingenious amalgamating device. We note also the name of Mr. John E. Rothwell, the nephew of the late Richard P. Rothwell, and himself honorably prominent in former days for his work in chlorination. Finally, Mr. W. E. Greenawalt, who contributed an article on patents in a recent issue of our paper, appears with another leaching process. Evidently many minds are on the alert to hasten metallurgical progress.

Panama Canal

On May 31 the local section of the American Institute of Mining Engineers was favored with an interesting account, by Mr. John C. Branner, ex-President of Stanford University, of the structural geology governing engineering work on the Panama Canal. Dr. Branner, as our readers will recall, was a member of the commission appointed at the end of last year by the President to investigate the cause of the landslips that have obstructed and endangered the Canal from the very first. The chief difficulty has been in the immediate vicinity of Gold hill, on the northern side of which is the big Culebra cut with its famous slides and on the southern side the equally important Cucaracha cut and its corresponding landslips. Not only has the Canal been blocked by the movement of the ground, but an area of fully 130 acres has been cracked and put into a condition of unstable equilibrium. The core of Gold hill, as of Contractor's hill on the opposite side of the waterway, consists of basalt of columnar structure, flanked by sedimentary rocks dipping toward it from all sides and suggesting contraction of the volcanic plug after cooling, so that the strata were first intruded, elevated, and then pulled down, just as if a gigantic nail of eruptive matter had been driven through the softer material. Wherever water penetrates the argillaceous sedimentary rocks they become soft and slippery, finally changing to an incoherent mobile mass, not much better than mud. On the south, or Cucaracha, side the movement continued until the angle of rest was not more than two or three degrees, while a little distance back the rock held firm; on examination the interesting fact was disclosed that several plugs of basalt, none of which reached the former surface, had served to restrain further movement. Whether similar geologic factors will come into play on the northern or Culebra side is not known as yet; if they do, they will prove most useful in retarding the slipping of the ground. This is caused, of course, by the seepage of water, of which not less than seven feet (not inches) falls per annum. This excessive rainfall begins in May and lasts till December, becoming heaviest at the end of the wet season, when the Canal is most imperilled. At the meeting, Mr. George L. Dillman suggested the running of an adit through the basalt of Gold hill and extending laterals into the moving ground in order to drain it. Dr. Branner declined to suggest any remedy, leaving it to the engineers to do so, but he indicated his belief that the speedy removal of the surficial water was of paramount importance. Professor E. A. Hersam made the pertinent remark that "it was better to shingle your roof than to pump out your cellar." Professor A. C. Lawson suggested the use of lime to destroy the mobility of the clay. Other ideas will be put forward and an earnest effort will be made to save the great work of engineering that promised to be one of the big things of the world, but, it must be confessed, the outlook is not nearly as cheerful as we would like it to be. Unquestionably the geologic conditions were insufficiently studied before the decision to build the Canal was reached, although it is true that the particularly unfavorable structure of Gold hill was not discernible until excavation had disclosed it; nevertheless, it is a fact that the engineering commission appointed under the Spooner Act in 1904 did detect signs of possible trouble and did give a warning, as was stated by Mr. C. E. Grunsky, a member of that commission, at the meeting to which we are now referring. Indeed, if the choice had lain between a lock-canal in Panama and one in Nicaragua, the latter would have been selected, and it was the first decision to build a sea-level canal that put the Nicaraguan

project out of court, not to be re-considered when the Panama scheme was changed to a lock-canal. We may well hope that the adverse conditions disclosed along the Canal, now that it is built, at a cost of $400,000,000, will be overcome by engineering skill and systematic energy, but many engineers are beginning to question whether it would not be cheaper to build a new canal in Nicaragua. Danger from earthquakes does exist. As Dr. Brauner indicated, the argument that these earthquakes need not be feared because one or two old houses remain standing in the town of Panama, and more particularly the well-known flat arch, is not at all convincing; but expert opinion is fairly unanimous in regarding the destruction of dams and locks, even by a severe earthquake, as highly improbable. Does the acquisition of a concession in Nicaragua presage a new canal enterprise? Whether it does or not, it is clear that "making the dirt fly" is not enough when Nature is ready to make the dirt flow at an equal rate, threatening to obliterate man's handiwork. Engineering advice was insufficiently weighed at the outset, as is now acknowledged. The Army engineers merely carried out plans too hastily accepted; their administration, of course, was splendid, but the damage had been done by bureaucratic muddling long before they took hold. The Canal remains an engineering problem half-solved; it remains to be seen whether the natural obstacles, at first lightly regarded, can be overcome so as to ensure an open waterway between the two oceans.

Tungsten

The reviews of mining progress in the Western states, as published periodically in this paper, have made frequent mention of a metal that was scarcely known to the average miner a couple of years ago, nor for the matter of that to persons supposedly even better informed, for in the latest issue of *The Annalist* we read about tungsten as a "mineral" and are told that it is "converted into an acid for the hardening of steel tools." By this time our readers know all about the minerals in which the metal tungsten exists as an acid radical, tungstic oxide. Tungsten is a Swedish word meaning heavy *(tung)* stone *(sten)*. The chemical symbol W is taken from the Latin *wolframium*. In California the chief ore is the tungstate of lime, scheelite, and it is a noteworthy fact that during recent months the most profitable mine in the State has been a tungsten enterprise, the Atolia Mining Company in San Bernardino county. In Arizona hübnerite and wolframite, the tungstates of manganese and iron, share economic importance with scheelite, while in Colorado, particularly in Boulder county, the mineral ferberite, a tungstate of iron, is the characteristic product. In all these minerals the content of tungsten tri-oxide (WO_3) ranges from 75 to 80%, the actual treatment of the ore yielding a concentrate containing 60 to 65%. This concentrate is reduced with carbon, together with iron ore, in an electric furnace, the resulting ferro-tungsten containing 75 to 80% tungsten. This is added to the charge when making certain kinds of steel. Alloy-steel, especially for high-speed cutting-tools, consumes most of the production. Another important use is as wire in the making of filament for incandescent lights; when used for this purpose a pure tungstic oxide is obtained by chemical process and then reduced at a temperature of 1000°C. by hydrogen or pure carbon, yielding a black powder that is pressed into bars through which an electric current is passed in order that the heat may agglomerate the metallic particles so that the bar can be shaped, becoming so ductile that it can be drawn into wire. Previous to the War, the world output of tungsten was about 10,000 tons of 60% concentrate; and out of this total Burma contributed 2700 tons, the United States 1390 tons, and Portugal 1380 tons. At the end of 1913, Portugal's output was increasing the most rapidly, having nearly trebled in five years. Until recently the manufacture of ferro-tungsten was mainly a German industry; now England is making supplies for herself and her allies. The placing of an embargo on the shipment of tungsten ores and products from England or her overseas dominions has had a beneficial effect in stimulating the mining and metallurgy of tungsten in the United States, where the making of high-speed tool-steel is at its maximum. Hence the extraordinary rise in price. During 1913 the price ranged between $6 and $7 per unit of 60% concentrate. In 1914 the average was $7 per unit. By the middle of February 1915 the quotation was $40, rising slowly to $50 in February of this year, when a jump to $105 per unit, or $5.25 per pound, was recorded. Whereupon there ensued a veritable scramble for tungsten ore all over the West; the resulting production, together with large shipments from South America, flooded the market so that the price declined rapidly until now it is at about $40 per unit. That incorrigible ratio of supply and demand has a way of asserting itself, despite all we may hope or dream.

The MacArthur-Forrest Process

Cyanidation and MacArthur are names so linked in the historical development of modern metallurgy that our readers will appreciate the appropriateness of an account of the discovery of the cyanide process by the discoverer himself. To these last words Mr. MacArthur will demur, for he shows himself anxious to give a large share of credit to his associates, notably Dr. Robert W. Forrest, whose name is usually joined with his to make MacArthur-Forrest synonymous with the beginnings of cyanidation. Our readers will like the article; it is written without any affectation, with a directness and a charm quite characteristic of one of the most useful of living technicians. It will be noted that the publication of a description of an electrolytic chlorination method was the first step toward metallurgical distinction. The pen is a lever for lifting men to a point of vantage. The next step was, he says, to make "plenty of mistakes" and "acquire knowledge" from them. Thus do metal-

lurgists rise on stepping stones of their mistakes to high achievement. The little band of investigators foregathered in a 'glory-hole'—in which unfamiliar use of the word the Western miner will find the origin of a term now glorified indeed. 'Glory-hole' is a corruption of 'glaury-hole,' a name given by Scottish sailors to the place for refuse in the waste of a ship. At our Western mines it became convenient to throw the discard from the boarding house into the nearest open-cut, so that the latter became a glaury-hole in the Scottish sense, which was soon forgotten in the fact that many open-cuts, as at the Alaska Treadwell and the Combination mines, were made by excavating rich ore. Thus the term became synonymous with mineral wealth. Much in the same way 'lumber-room,' a garret for storing odds and ends, came to us from 'Lombard room,' a shelter for Lombard refugees. Thus do words wander from their origins. We apologize for the digression. The next point is more important: the founders of the cyanide cult made it a rule, in their search for a workable process, to regard no gold as extracted that was not "put on the table." That showed their hard-headed sense: it was a good plan to follow, but it was nearly over-done. Mr. MacArthur relates how their epoch-making discovery was delayed a year by the fact that they relied so much upon the recovery of the gold as bullion "on the table" that they failed to assay the tailing from the first experiment in which potassium cyanide was used and assumed a failure from their non-success in precipitating the gold when employing an ineffective reagent, namely, sulphuretted hydrogen. The discovery came when the residue from similar experiments was assayed in October 1887.

These investigators knew what they wanted, namely, a solvent that would dissolve the gold without attacking the encasing sulphides, in short, one that would "hold the gold against all comers." Heretofore experimentation had been confined to metallic gold, by itself, using reagents that were impracticable in the presence, for instance, of pyrite. Again, the process had to be cheap, therefore it could not depend upon the help of roasting, which is "neither simple nor cheap." Of course, the solubility of gold and silver was a matter of encyclopedic record; what MacArthur and Forrest did was to prove that a solution dilute enough to be cheap would effect the extraction, and they followed this by providing the means for precipitating the dissolved metals so that they could be collected as bullion. It was the use of zinc in an easily soluble form that made cyanidation an immediate success. Mr. MacArthur makes mention of the prescience shown by Mr. Louis Janin, Jr., who is still with us, although unfortunately withdrawn on account of ill health from participation in the metallurgical research for which he exhibited such signal ability in his early manhood. In our interview with Mr. Hennen Jennings, last December, a mention was made of the first trial of the process at Johannesburg, and Mr. MacArthur now gives a whimsical account of the test, together with a friendly handshake across the years with the chief sceptic. The mention of Elsner's blunders and how they were perpetuated in books of reference recalls the fate of feldspar, which became 'felspar' by the dropping of the 'd' in Kirwan's 'Elements of Mineralogy,' published in 1784. It is evident that MacArthur and his friends did not allow themselves to be side tracked by Elsner's mistakes, nor did they permit themselves to be misled by chemical subtleties; they aimed consistently to find a real metallurgical process, namely, one to extract gold from ore economically. Therefore they did not assume that the reaction between cyanide and gold was on all fours with the effect of potassium cyanide on gold incased within the sulphide minerals of the base metals. They persevered, doing their work while all the (other) respectable people of Glasgow were asleep, energizing themselves occasionally with the weird concoction provided by Dr. Forrest, of which we can say, having consulted the family physician, that it was a respectable medical cocktail.

It is 29 years since the cyanide process was given to the miner by MacArthur and the two Forrests. Not long ago fully 60% of the world's annual production of gold was being extracted by it and the world's greatest goldfield—the Rand—while yet in its infancy was developed by aid of it. What gold mining in South Africa would have been without cyanidation, we do not know, but it is quite certain that the industry would have remained puny and sickly as compared with the magnificient growth since 1890. The troubles over patent rights were settled in due course, and it is only fair to add that in the case of cyanide, as in that of flotation, it was not the discoverers of the process but the purchasers of the patents, in the guise of royalty-gathering companies, that made most of the trouble. Indeed, the absurd claims made for the process by the first American exploiters of it and their crass ignorance of the operations involved were such as to discredit cyanidation in the West, 25 years ago, as was related by Mr. Philip Argall in the interview we published last January. For the rest, most of us will recall our astonishment when we first found out that we could extract gold from a pyritic ore without any apparent chemical change in the ore. The pleasure of those early experiments and experiences has never been quite staled by frequency. In a faint way we can imagine the keen delight of the little group of earnest investigators who, in October 1887, suddenly placed a finger on an epoch-making fact. Such moments are rare in life. Moreover, that early work disclosed the basic idea: the chemistry of cyanidation is in essence much as it was ascertained then, the progress of later years being mainly in the line of mechanical improvement. Undoubtedly the cyanide process reached a high state of chemical and mechanical efficiency in the first decade of this century; it has, we believe, seen its best days, because flotation is destined increasingly to invade its domain, just as cyanidation previously invaded that of amalgamation. It was a good time to tell the story of the discovery and to express the gratitude of the profession to the discoverers.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Electric Theory of Flotation

The Editor:

Sir—Mr. Fahrenwald's article, 'Electro-Statics of Flotation' in your issue of March 11 is very interesting, and I consider his criticism of Bains's electro-static theory most opportune, but in the course of his criticism he attempts to prove that the electro-static charges present on the surface films cannot be great enough to effect flotation: an assumption which, if true, would discredit all electric theories. I do not in the least agree with his line of reasoning in this matter, and shall confine myself to this point. Mr. Fahrenwald makes absolutely no distinction between electro-static units of quantity and of potential. These are as different as the coulomb and the volt, and either can exist in large amounts without necessitating a large amount of the other. An electro-static unit of quantity is a quantity of electricity which will repel a similar quantity of electricity separated from it by a distance of one centimetre of air with a force of one dyne. It has been proved experimentally and theoretically that it takes 3,000,000,000 of these electro-static units of quantity to equal one coulomb. Now the electro-static unit of potential is correspondingly large. It is a difference of potential of such magnitude that one erg of work is required to move one electro-static unit of quantity through this difference of potential. Since a coulomb is one-tenth of an absolute electro-magnetic unit, and since a volt is 10^8 absolute electro-magnetic units, an electro-static unit of potential equals 300 volts.

Mr. Fahrenwald calculates that a charge of 25.9 electro-static units of quantity must be present on the surface of the air bubble in the particular case he takes up. He then takes up the distances that various differences of potential will discharge through, and shows that 25.9 electro-static units of potential will discharge through a fraction of a centimetre of air. Both of these statements are perfectly true, but it is possible to have practically any quantity of electricity at practically any potential difference, if we care to build a condenser to suit the requirements. To take the particular case of a bubble of air in water, probably the best known work on this subject is that of H. A. Taggart, published in the *Philosophical Magazine*, 1914, 27:297 and 28:367. He found that an air-water surface film had a difference of potential between its two sides of 0.055 volt, and that the surface density of the charge was 0.00004 coulombs per sq. cm. If we convert these into electro-static units we see that the density of the charge is 12,000 electro-static units per sq. cm., and that the difference of potential between the two sides is 0.00018 units of potential. It would be useless to multiply instances similar to this. The molecular forces bound up in surface films are nothing less than enormous. While they may ordinarily be 'bound,' that does not in the least prevent our putting them to useful purposes, as is done in flotation.

Gold From Atlin Mines

The Editor:

Sir—With regard to the total quantity of gold from placer mines of the Atlin district, I think Messrs. Chester F. Lee and T. M. Daulton have inadvertently understated the value, which they place at $4,518,000 in the interesting paper of which you printed an abstract in your issue of May 13 (p. 721). The British Columbia official records, as printed in the annual report of the Minister of Mines, will, I think, be found to give a total to the end of 1914 of $6,163,000; add the amount for 1915, $377,000, which most likely has not yet been published. Thus a total of $6,540,000 is obtained, not $4,518,000 as given by the writers of the paper quoted from. This larger amount, I take it, is the total of recovery from all the creeks in Atlin mining division, for all years, 1898-1915, both inclusive.

Victoria, B. C., May 15.

Mining Law

The Editor:

Sir—Apropos of the proposed revision of our mining laws, it is to be regretted that American legal practice cannot reconcile itself to simplicity. Our mining laws as at present enforced lend themselves notably to endless litigation. Decisions are rendered on the most absurd technicalities: in numerous cases it seems that it is not justice that is sought, but the vindication of legal fictions.

The proposed legislation seems not to be a great improvement; yet it must have some positive virtue, for the newspapers chronicle a meeting of Colorado legal talent for the express purpose of combating the new legislation. This sinister conference has not yet defined its attitude toward mining law as it stands at present,

but one need only glance over the 'stand pat' attitude of the legal fraternity toward every proposed change in legal practice to be assured that anything save a rigid adherence to present practice will be met with howls of derision, not to say graver charges.

What should distinguish our mining code is simplicity, add to that certainty. A long step in that direction would be taken if the Federal Government were to adopt the British Columbian practice of making locations 1500 ft. square and abandoning the principle of extra-lateral right. The principle of extra-lateral right is a bugbear, a snare, and a delusion. Evolved from the brain of a capable brilliant lawyer, and through his remarkable ability and powers of persuasion made to serve his ends, it has continued on its pernicious course nearly 50 years; no other single feature of our mining law has been so prolific of discussion and the accumulation of fees.

I can not understand why the B. C. system is not more strongly supported by mining men. The system of posting is as good as our own and lends itself equally to wooded and desert country. It gives ample room. Fifteen hundred feet square on a vein is enough for any one, if the vein proves good; if it isn't good it makes no difference.

Midas, Nevada, May 25.

A Quick Method of Locating Geologic Features

The Editor:

Sir—In your issue of May 20 Mr. Charles A. Porter describes 'A Quick Method of Locating Geologic Features.' Mr. Porter states "in the examination of prospects, an approximate method of determining the position of landmarks is often desired." I believe that where the prospect has economic possibilities, or in case the engineer is making a preliminary report to clients who are not familiar with the property, a map is necessary. On such a map the approximate location of landmarks and geologic features is essential and always desirable.

The triangulation system described is commonly called the 'two point' method by those familiar with plane-table surveying. Locations made in this way are fairly accurate when the angle formed by the intersection of the two lines at the unknown point is about 90°. Better locations are determined by the intersection of three or more sights toward the unknown point.

Having determined the location of several stations by this method the observer can occupy a vein outcrop or other geologic feature and determine its approximate position with reference to the established stations by the intersection of the lines from such stations, the bearings of which are determined from the unknown occupied location, and so on *ad libitum*.

It is advisable to plot the lines in the field, using a small protractor during the course of the examination. If done at that time many geologic data of value to the examination will be collected and properly tied to the map as the observations are taken. These data will be of inestimable value to the report, as factors from which to appraise the prospect investigated. The whole method as here described and as set forth briefly in your issue of May 20 has been used by engineers and geologists for many years.

San Francisco, May 23. Leon J. Pfefferberg.

Discussion should be one of the most important things in the world, for it is almost our only arena of thinking. It is here that all the jumble of ideas and impressions that we get from reading and watching are dramatically placed in conflict. Here only is there a genuine challenge to put them into some sort of order. Without discussion intellectual experience is only an exercise in a private gymnasium. It has never been put to the test, never had to give an account of itself. It is some such motive that impels people to discussion; though they are too often content with the jousting of pasteboard knights. But a good discussion is not only a conflict. It is fundamentally a co-operation. It progresses toward some common understanding. This does not mean that it must end in agreement. A discussion will have been adequate if it has done no more than set the problem in its significant terms, or even defined the purpose that makes such a setting significant. You turn up things in your mind that would have remained buried without the incision of some new idea. The effort to say exactly what you mean, sharpening your idea to the point that will drive home to others, is itself invigorating. A good discussion tones up your mind, concentrates its loose particles, gives form and direction. When all say exactly what they mean, then for the first time understanding—the goal of discussion—is possible. Discussion demands a mutual trustfulness, a mutual candor. But this very trustfulness makes discussion vulnerable. It is particularly open to attack of the person who sees in the group a forum. The physical signs of such a misinterpretation are familiar. The eye becomes slightly dilated, the voice more orotund. The suggestion develops into an exposition, the exposition into an apologia or recrimination. Discussion is slain. Another enemy is the person who sidetracks a sentence and then proceeds in a leisurely way to unload its freight into his own wagon. But in a good discussion the traffic is kept constantly moving in both directions along a rather rigid line of track, and the freight arrives somewhere. Some people have a fatal gift of derailment. Wit is perhaps the most common means. Discussion has no greater enemies than those who can catch an idea and touch it off into a puff of smoke. Wit should salt a discussion but not explode it. Good discussion is so important that those who set about it may be rather pedantic and self-conscious in their enterprise. One may acutely realize oneself as being, for the time, primarily a mind.—Randolph Bourne in *The New Republic*.

The Discovery of Cyanidation

By John S. MacArthur

MY training in practical chemistry and metallurgy began in the Glasgow laboratory of the Tharsis Sulphur & Copper Co. This company owns mines of copper pyrite at Tharsis and Calanas in the south of Spain. The ore is high in sulphur and iron, low in copper—not over 2%—and contains small quantities of gold and silver, say, 0.025 oz. and 1 oz., respectively. The pyrite is shipped to various chemical centres in Britain and the continent of Europe, where the sulphur is burned off to make vitriol, while the cinder—often called 'burnt ore'—is returned to one of the extracting works of the Tharsis company that are dotted over the country in the chemical centres. The 'burnt ore' is mixed with salt and roasted to solubilize the copper and leave the iron as ferric oxide, called 'blue billy' in this form, which is insoluble in water and weak acids. In the course of salt-roasting the gold and silver are chloridized, the gold imperfectly and the silver perfectly. The heat is only a dull red, but at this temperature a variable proportion of the copper, about 10%, is volatilized and condensed by a descending flow of water in a coke-tower. The copper vapor entrains the aurous chloride and anhydro-chloric acid, both of which are formed in the roasting. The silver chloride resists volatilization at this temperature and remains with the insoluble iron.

It fell to me to make a research, under the guidance of my chief, the late R. A. Inglis, to see if it were possible to recover the gold from the aqueous acid solution of copper without materially affecting the copper or the acid. We found that this could be done by adding a minute quantity of a soluble sulphide that precipitated its equivalent of copper sulphide and at the same time entrained all the gold, leaving the liquor practically unaffected and ready for its next duty of washing out the basic salts of copper, which are not soluble in water, from the mass of roasted ore, now transferred to lixiviation tanks.

This process is called the Longmaid or Henderson, after the two men, who, at different times and in different circumstances, had elaborated its leading principles. It is in general use in Europe, but in America is employed only in the Eastern States.

Besides this method of gold extraction, I had to investigate various methods of extracting gold devised by men who assured us that the pyrite contained much more gold than we imagined. All these methods, whether propounded in good faith or bad, came to nothing, but thus it was that I became familiar with the industrial chemistry of gold and some of the problems of gold extraction, though at this time I had not even seen a gold mine.

About 1885 the Cassel Gold Extracting Co. was formed at Glasgow to develop a patented process for the extraction of gold from refractory ores. This process was essentially one of electrolytic production of chlorine from weak brine in presence of the ground ore, with simultaneous electrolytic precipitation of the gold. In the summer of 1886 the inventor, H. R. Cassel, disposed of his interest and left Glasgow, leaving the company in a state of chaos. I made a research on the subject in the premises of a friendly electrician who gladly gave the facilities. As a matter of fact, gold was extracted, but I had no data as to efficiency of action or as to cost. In a weak moment I yielded to the persuasion of a friendly journalist and published (anonymously) the result of my essay. Very soon it leaked out that I was the writer and I was asked privately if I would disclose myself to the Gold Extracting Co. For various reasons—one of them being that I had not sufficient grip of the subject—I declined.

My friends, the brothers Robert W. and William Forrest with George Morton, advised me to continue researches on gold extraction, promising co-operation and support. We soon formed ourselves into a research syndicate, each of us having an equal financial responsibility as to cost, but Mr. Morton guaranteed my salary in case it should be necessary for me to give up my situation with the Tharsis company. We certainly were not capitalists, only a quartet of enthusiasts carrying out research in the evenings in a glory-hole under the consulting rooms of the two Forrests, both of whom were doctors. We worked hard and made plenty of mistakes, but kept on acquiring knowledge and gathering data.

The Gold Extracting company was still under a cloud, an influential shareholder in it and in the Tharsis company pressed to be allowed to introduce me to William Verel, who was both the general manager of the Tharsis and an honorary director of the Gold Extracting company. I declined his introduction respectfully but said that as Mr. Verel was my own 'governor,' I would see him myself. He was surprised to know that the chief assistant in his own laboratory had investigated the subject and, the two companies being on the most friendly terms, I soon found myself transferred to the Gold Extracting company as technical manager while still retaining the goodwill of my Tharsis friends. It was a condition of the engagement that my new employers should have the first call on any invention or discovery resulting from the work of the MacArthur-Forrest research syndicate, but the Gold Extracting company assumed no responsibility as to the expenses unless it took over the problematical invention looming in future, at least in the Syndicate's dreams. It will be seen that the assistance of the capitalist did not arrive until after the in-

vention had been made, proved, and taken over. The whole burden of research was on the shoulders of our quartet.

The Syndicate resolved not to use electricity, as my one short experience of the difficulty of applying the electric current to a mass of sodden ore was quite dissuasive. All the same, I did my best for a year to make electrolytic chlorination an industrial possibility. An occasional flash of success lured us on time after time, but the work was disheartening; we might get a good result on an ore from India or Victoria, but not on ores from Peru or Queensland.

The Research Syndicate laid it down as a rule that we would not reckon gold extracted as the difference between the assay of the original ore and that of the tailing, but in every case the gold must be put on the table. We were methodical; we tabulated our program of possible solvents, including many chlorine and bromine mixtures, so devised as to minimize the action of chlorine or bromine on the pyritic minerals always associated with the average gold ore. These mixtures were more or less successful but never to the point of uniform success.

We never thought of using *aqua regia* as a solvent of gold in ores; we knew very well its powerful action on gold, but that concerned us very little, for we knew that in inter-action with it the pyritic minerals took preference; and if by any chance a little gold was dissolved, the metallic sulphides and even some metallic oxides precipitated it at once and restored the *status quo*. Anyone can find a solvent for gold, but until we undertook our researches no one had suggested the possibility of a simple solvent that would primarily attack gold and shun base sulphides. We thought that the resources of chemistry were not exhausted, and we searched for this hypothetical solvent.

At an early stage in our work, during November 1886, we used cyanide of potassium as a solvent and followed our rigid rule of putting the gold on the table. We invariably used sulphuretted hydrogen as the best all-round precipitant and did so on this occasion, forgetting that it does not precipitate gold and some other metals when they exist as cyanides. This trial was put among the non-successes; the residue from the cyanide treatment was, like many others, wrapped neatly in paper, labeled, and put on the shelf.

Nearly a year passed when, in October 1887, I had occasion to separate gold from mercury in a cyanide solution. As the separation was being made I recalled our cyanide trial eleven months before. Cyanide solution was again tried on one ore and another and another, and to our delight the residues showed a full extraction. We then went to the shelf, selected the parcel of residue that had been sleeping there holding its secret for nearly a year, assayed it, and found no gold. Then followed the usual hurry and excitement of consultation with the patent agent, drafting of specifications, and the plunge into the sea of troubles that awaits the successful inventor.

The Mac Arthur-Forrest invention was covered by two British Patents: 14174 of October 19, 1887, and 10223 of July 14, 1888. The principal points covered were:

1. Treatment of the powdered ore with a weak cyanide solution.

2. Drawing off the gold-bearing solution from the treated ore.

3. Precipitation of the gold by zinc.

Among all the mass of 'anticipations' unearthed by the lawyers, not one prescribed the simple treatment of ore with a simple cyanide solution, and none prescribed drawing off the solution for precipitation by zinc. Cyanide was invariably associated with some other chemical agent, or as an electrolyte, or as a means of removing base metals or of grease, but never as a simple solvent of ore-locked gold or silver.

The one man who had any idea of the possibilities of cyanide was Louis Janin, Jr., who, on December 21, 1889, more than a year after we had recorded our invention at the British Patent-Office and a few months after our publication, wrote an article in the *Engineering and Mining Journal* of New York, in which with remarkable prescience he adumbrated some of the principal features of cyanide practice, for example, he indicated not only that a cyanide solution is a powerful solvent of gold and silver from their ores, but that a weak solution is better than a strong one, and that the base metals are more easily attacked when the ore is roasted.

Before the end of 1888 the Gold Extracting company had sent expeditions to Queensland and New Zealand, while I went to America. The first cyanide gold was banked at Ravenswood, Queensland. It was extracted from some foul tailing by the adaptation of an old pan-mill equipment. The first cyanide plant, designed as such, was erected for the Crown Mines, at Karangahake, in the North Island of New Zealand. As this mine is still being worked, I presume that the old plant is still in evidence. [The Crown property was closed indefinitely early in 1916.—Editor].

In America the process was received with frank incredulity, and while the inventor had no reason to complain of any lack of politeness, it was so mixed with the kindly forbearance usually meted out to ill-informed enthusiasts that he often felt most uncomfortable. The American view was well put by W. D. Johnston in the Report of the State Mineralogist of California for year ending December 1, 1890. In the course of a most interesting article he wrote:

"The claims set forth in the above article undoubtedly caused great surprise to the chemists as well as to the mining engineers of the civilized world. That cyanide of potassium would dissolve metallic gold and silver, forming soluble double cyanides of gold and silver, had long been known to chemists and electroplaters, and the double cyanide of gold and potassium is now the favorite solution of gold used in gold-plating. That a dilute solution of cyanide of potassium would extract gold and silver from their combination in sulphurets of iron, etc., leaving the sulphurets apparently unchanged by this treatment, was certainly an amazing statement, and just-

ified to a great extent the incredulity with which chemists received the article, and the refusal of many of them to test the truth of the statement for their own satisfaction.

"The writer confesses to have shared in the doubts of the majority, and for a time looked upon the subject as a companion of the schemes attempted to be palmed off on our capitalists by Alfred Paraf, of oleo-margarine fame; Major Tichenor, of Calistoga notoriety; Robertson (*alias* potassium cyanide), of San Francisco; and the 'green gold' swindlers of San Rafael."

Soon after the expeditions to Australia and New Zealand, the Gold Extracting company despatched Al-

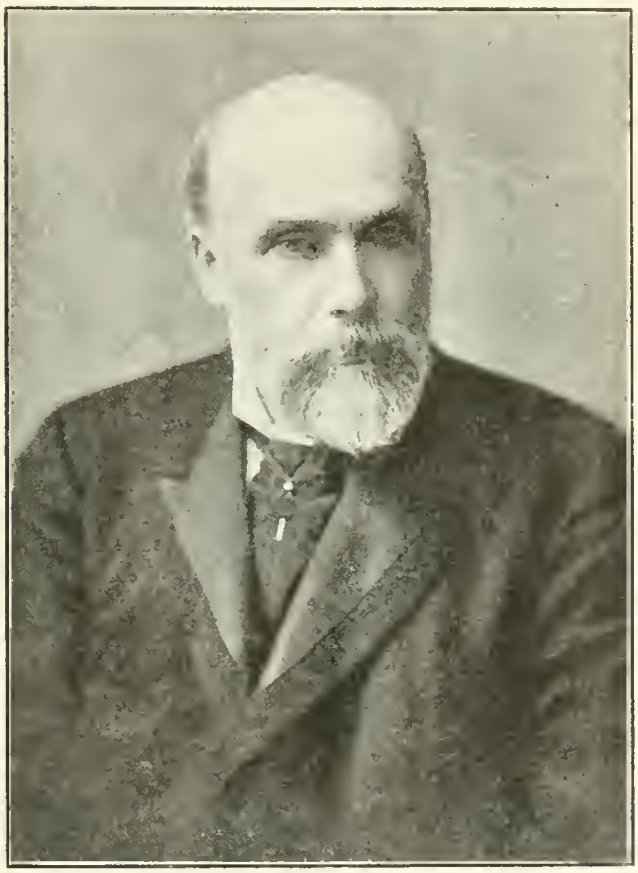
JOHN STEWART MACARTHUR.

fred James as scout and pioneer to South Africa. At this time Barberton was waning and Johannesburg, only three years old, was asserting itself as the centre of the gold industry. In a few months James returned, reporting that there was a good field for the process and that a small syndicate, afterward called the Gold Recovery Syndicate, was ready to take up the process of the Gold Extracting company, and would prove it on the spot to its satisfaction. A great demonstration was arranged for the following year. James went out with the plant and a small squad of mechanics and when the plant had been erected I followed in May 1890, and superintended the demonstration. We had several classes of ore and tailing to work on, but our great triumph was on the Percy concentrate, which was almost wholly arsenical iron pyrite containing 20 oz. gold per ton. Our extraction was 98%. As described recently by Hennen Jennings,* the

*M. & S. P. December 25, 1915, Page 964.

cyanide treatment was by agitation—an extravagance justified by the high grade of the material. Then, as now, we worked ordinary tailing by percolation.

A big group of engineers and metallurgists attended at the Salisbury battery to assist at the demonstration. They were all determined to "see it through," and were excessively zealous for an hour or two, but as afternoon merged into evening and evening into night, "important engagements," "urgent business" and "headaches" dragged them away one by one until Jennings and I were left alone; even Alfred James was down with a touch of



ROBERT WARDROP FORREST, M.D.

fever that night. At the beginning Jennings made it quite clear that he was there to watch and check everything and everybody, especially myself. I told him that we would be quite happy together—and we were. For three days and two nights we worked, ate, and rested together, and then began the friendship that remains unbroken. I was fortunate in having such a man to investigate our process and from that day to this I have regarded Hennen Jennings as the embodiment of strength, honor, and fair play. It was a fitting and happy coincidence that in 1903, he, as President of the Institution of Mining and Metallurgy, should hand me the medal of the Institution on the occasion of its first award. He is right in saying that the use of dilute solutions was the key to the success of the process, but perhaps it is not clear to him and to others that, prior to our first British patent, there was an utter absence of knowledge concerning the power of cyanide in weak or strong

solutions to dissolve gold and remove it from its base associates in gold ores. All through I had known of the power of zinc to precipitate gold from cyanide solutions, but this power is exerted so feebly that the use of ordinary zinc sheets for this purpose was impracticable, and we used zinc saw dust produced by milling cakes of cast zinc. It did well, but it was far from perfect. As a boy I had bought a pennyworth of fine zinc ribbon to burn as a cheap substitute for magnesium ribbon and now to my regret found that magnesium had become so cheap, or boys so rich, that zinc ribbon was no longer to be had. I had confided the trouble to our foreman mechanic, who, one day, in making a zinc case for packing blocks of cyanide, made a thin shaving while using one of his tools, he then made a handful, brought them to me, and the thing was done.

The further history of cyanide in South Africa is a story still being told volume by volume as the years pass.

The Gold Extracting company had from the start to manufacture cyanide for consumers. Previously it had been made by the pound as a fine chemical, now it was demanded by the ton. The Germans, quick to appreciate a good thing, even if new, immediately went into the trade, made an excellent article, tried to oust the Gold Extracting company, which stoutly held its own, until today it is the Cassel Cyanide Co., producing the best cyanide in the world.

Among those who helped to introduce the MacArthur-Forrest process and still survive are Dr. R. W. Forrest, George Merton, co-inventors; A. Forson Stewart and H. M. Leslie, research assistants; W. Dempster, a New Zealand pioneer; C. J. Ellis, who took the process to India; William Jones, a South American pioneer; and W. A. Caldecott, who assisted at the Salisbury battery in 1890 and has for years been one of the leading metallurgical authorities on the Rand.

The use of cyanide in metallurgy is not yet fully developed, but for the present I am content to enjoy the reminiscences of the past.

---

*The guidance on this subject to be obtained from chemical and technical text-books was scanty, meagre, and sometimes misleading. The standard books of reference on chemical matters must copy largely from a few original sources, and if an inaccuracy or error occurs at the fountain-head, it is sure to be perpetuated. We could get no information whatever on the action of cyanide solutions on gold ore, and no direct or useful information as to the action of cyanide on the ores of base metals. We did get, however, some information regarding the action of cyanide solutions on the metals themselves. For instance, Elsner states (*J. Prakt. Chem.* 37 (1846), 441) that iron is soluble in cyanide solution and mercury is not acted on—both statements palpably erroneous. Other investigators stated that mercury was dissolved in cyanide solution, but the fact that commercially pure iron was not appreciably acted on was first noted, I believe, in the course of my own work. Possibly the iron used by Elsner contained some silicon—if so, hydrogen would be evolved, but no iron would be dissolved.

There was a similar confusion as to the action of cyanide solution on gold. Elsner stated that oxygen was necessary for the reaction. Percy (referring to silver) says that either hydrogen is evolved or oxygen derived not from the air, but from any cyanates that might be present. (Percy's 'Metallurgy,' Part I, pp. 111-115.) Gmelin also thinks the cyanates may supply oxygen. Faraday indicates clearly that air contact and the formation of air voltaic circles are necessary for the reaction. He does not hint at any oxidizing action being necessary (Phil. Trans. Vol. 147, p. 147). As Faraday may fairly be taken to represent the high-water mark of knowledge on this subject in his generation, I think it well to quote his words. Referring to the dissolving of gold leaf in cyanide solution, he says:

"Air voltaic circles are formed in these cases, and the gold is dissolved almost exclusively under their influence. When one piece of gold leaf was placed on the surface of a solution of cyanide of potassium, and another, moistened on both sides, was placed under the surface, both dissolved; but twelve minutes sufficed for the solution of the first, whilst above twelve hours were required for the submerged piece. In weaker solutions, and with silver also, the same results were obtained: from sixty to a hundredfold as much time being required for the disappearance of the submerged metal as for that which, floating, was in contact both with the air and the solvent. An action of this kind has probably much to do with the formation of the films to be described hereafter."

These references and all others available referred to the action of cyanide on metallic gold with which we had little concern, and did not touch on its behavior toward ores or the minerals usually found in ores. Amid all this confusion of authority, we had to work out a metallurgical process rather than attempt to solve delicate chemical questions concerning reactions among pure materials.

On the general assumption that the addition of oxygen, or at least air contact, was necessary for the chemical action, we constructed our first apparatus with a wonderful arrangement of ploughshares which turned the ore, sloppy with cyanide solution, over and over, always exposing fresh surfaces to the air. This apparatus gave such good results that we tried the simplification of plain stirring, which also did well, and we came down to a revolving barrel, which did equally well. After this we came down to a plain percolation of the cyanide solution through the ore, which gave such satisfactory results that we concluded that, even if air contact or oxygen were necessary, it was not necessary to devise any special form of apparatus to introduce air to the mixed ore and cyanide solution. Thus all special mechanism was eliminated and the process be-

*Abstracted from the Journal of the Society of Chemical Industry, April 15, 1905, from a paper entitled 'Gold Extraction by Cyanide: A Retrospect,' by John S. MacArthur.

came less of a complex process and more of a simple operation.

While this practical work was being carried on, the chemical aspect was not neglected. Experiments were carried out on ores treated with cyanide solutions which had been made from water boiled to expel all dissolved air, and the extractions were the same as under normal conditions. At this time I also suspended a sheet of gold by a fine thread in a cyanide solution, about an inch under the surface of cyanide solution, and found that it dissolved surely and steadily. It was clear that there was no need for air contact, and as no one had ever suggested that air or oxygen was dissolved and held unchanged in cyanide solution, all appearances went to show that the chemical action was independent of oxygen.

A GROUP OF CYANIDERS WHEN THE PROCESS WAS ONLY THREE YEARS OLD. IN FRONT, J. S. MACARTHUR HAS ALFRED JAMES ON HIS RIGHT AND C. J. ELLIS ON HIS LEFT.

At that period I expressed my opinion on the subject to this section, thus: "Elsner has stated that metallic gold dissolved in cyanide of potassium only in the presence of oxygen. Not having seen the original account of Elsner's researches, I am not in a position to criticize his experiments, but I never could find that the presence of oxygen was necessary either to dissolve gold by itself or from ores by cyanide. If a piece of gold be immersed in cyanide solution, so that air to act on it would have to penetrate two to three inches of the solution, the gold will dissolve in its usual slow and steady fashion. The equation shows that either oxygen must be absorbed or hydrogen evolved. I have seen no evidence of the former, and can adduce no proof of the latter; but I think the latter the more probable, because I cannot conceive oxygen penetrating even a film of cyanide solution without at once oxidizing the cyanide to cyanate. * * * However, we do not concern ourselves much with the reactions of pure gold, but, as a matter of fact, we cannot find that oxygen plays any part in the cyanide extraction of gold from ores. We have treated an ore with cyanide with free access of air, and then a parallel experiment was done with boiled water, the bottle filled to the stopper with solution and ore, and the stopper sealed. The extraction was the same in both cases."

Over and over again this guarded statement of a reaction, avowedly imperfectly understood, has been construed into an absolute assertion that oxygen was unnecessary.

The question was solved as regards metallic gold *per se* by MacLaurin of Auckland, New Zealand, who discovered the fundamental fact that oxygen remained uncombined in aqueous solution along with cyanide, and did not, as generally stated and assumed, oxidize the cyanide to cyanate. (Proc. Chem. Soc., 1893 [122], 81.) He confirmed the equation usually attributed to Elsner:

$$2Au + 4KCN + O + H_2O = 2AuCNKCN + 2KOH$$

The cyanide process had been in general and increasing use several years before MacLaurin instituted his research, and the fact of its economical working proving the stability of the solutions in spite of protracted air exposure naturally carried with it the suggestion that,

assuming the necessity for oxygen in the chemical reaction, it must be soluble unchanged, in the cyanide solution. It was however, left to MacLaurin to prove definitely what had been mistakenly called Elsner's equation, which, in justice, now ought to be called MacLaurin's equation.

As a matter of fact, Elsner does not give this equation. Previous experimenters, myself included, had not reckoned on oxygen being held free and in solution in cyanide solution, but had gone on the text book assumption that cyanide solutions readily absorbed and combined with oxygen to form cyanates—another mistake. In practice, cyanide solutions of the fixed alkalies are now found to be stable in air for all ordinary purposes.

There is a strong general tendency to assume that the reaction between cyanide and metallic gold is reproduced exactly in the case of the gold contained in ores, and this general assumption has often obscured metallurgical investigation. No allowance has been made for the number and variety of mineral substances, possibly inacted on themselves, but still capable of modifying the reaction between gold and cyanide. Highly suggestive work directed toward the elucidation of this complicated problem has been carried out by Gore, who found that metallic gold was dissolved more quickly when in contact with some minerals than with others, and that such inert substances as ground glass and sand had a distinctly accelerating influence. He found that a gold disc lying on clean white sand dissolved nearly five times as quickly as when immersed in cyanide solution. What is the nature of the action in this case, I do not pretend to say. No one has yet suggested that sand has any chemical action under the circumstances. Possibly they occlude oxygen—I cannot say.

Another investigator found that the merest trace of ferric oxide induced the action. Again I do not pretend to explain; but, if this is so, the comparatively easy and rapid dissolving of gold from ores is accounted for, as practically all auriferous ores contain more or less ferric oxide.

Acting on the assumption that the chemical action is the same in the case of gold ores as in the case of gold already extracted, refined, and prepared, many propositions have been made to apply air or oxygen by mechanical means to the ore and cyanide mixture—compressed air in all forms, mazes of perforated pipes and stirring apparatus have been tried in all countries; but, as far as I know, not one has been worth the trouble involved or has justified its existence, and all have therefore dropped out.

Many chemical means of oxidation have also been suggested—peroxides of barium and calcium, bichromates, and even nitroglycerine; but they are little heard of now.

Other methods of oxidation (without oxygen) have been proposed, by which cyanogen has been generated direct to combine with the gold. The principal of these are the addition of ferricyanide (of any alkali metal) to the usual cyanide solution, used in the laboratory by myself, but afterward independently worked out and patented by Moldenhauer in 1892; and bromide of cyanogen suggested by Dr. E. J. Mills to myself in 1888; but independently worked out by Sulman and Teed in 1894-'95. This last method—the Sulman-Teed—is the only modification of the original cyanide process as invented and described by the Forrests and myself that has taken root. It has been found of great utility in working the tellurides of Western Australia, but not much heard of elsewhere.

So far, we have dealt with the problem of getting the gold into solution, which is by far the most difficult part of the question. The precipitation from solution is comparatively easy. We knew well that zinc precipitated gold from its cyanide solution; but it remained to make this reaction industrially applicable. We used various forms of finely divided zinc with more or less advantage; but a picture of some fine zinc shavings, bought with other things in a shilling box of chemicals in my boyish days, haunted my mind, and repeatedly I described it to one of the works foreman without effect, until one day, when making a zinc case for packing cyanide, he made a shaving by a sharp tool and came asking me if this was what I wanted. My reply was "Yes," and in half an hour he had prepared the first bundle of zinc shavings for gold precipitation—the pioneer bundle of hundreds of tons of this flimsy but useful material.

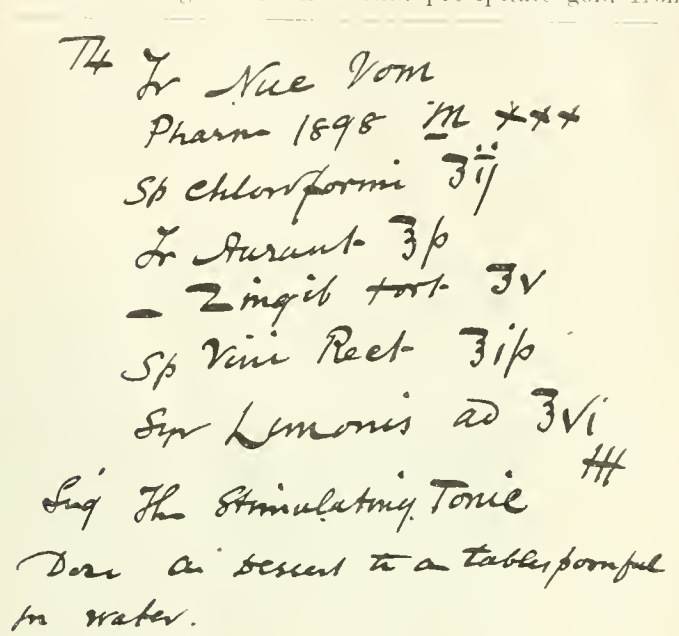
We had, of course, to design an apparatus for using the zinc. Here the difficulties of small-scale work hampered us seriously. It seemed such an easy matter to put the zinc in a jar with a hole at the bottom and allow the gold-cyanide solution to run through it; and this simple scheme did very well for a few hours; but gradually the interstices in the zinc mass became choked with extremely fine precipitated gold, the solution flowed more and more slowly, till finally the zinc mass became impervious and the solution overflowed. A small tank, really a water-tight box with a compartment arranged for the well-known alternate up-flow and down-flow, was used; but the down-flow compartments did not work satisfactorily. Finally the form now in use, in which the down-flow is through zincless compartments and the up-flow through zinc-full compartments, was devised in its first form by the metallurgists then in charge of the MacArthur-Forrest installation in New Zealand. It was modified in detail by myself, to economize space and give ease of working, and was used in 1890 in substantially its present form.

Zinc precipitation is one of the weak points in the process. With care, the precipitation is complete to a few grains per ton, but the gold is collected in such fine mud, drying into dust, that loss is inevitable. Various modifications have been suggested in the method of precipitation, to avoid this and other inconveniences. Zinc itself has been used in the form of a fine dust which was mixed with the cyanide gold solution into almost an emulsion. The gold was quickly precipitated and the gold precipitate with a large excess of zinc allowed to settle, and was then collected. This, however, did not

get over the trouble of the gold being in soot-like dust, likely to loss with each breath of wind.

*Unfortunately, I have no photograph of the early period of cyanide work. At that time we did not realize to what extent we were making history. The principal researches were carried out in the lowest flat of a tenement at 319, Crown street, Glasgow, a place little better than a cellar that had the supreme advantage of no front door and therefore no distraction from visitors. We did most of our work between 8 p.m. and 2 a.m. when the Forrests had finished their day's work, as I had finished mine. It was usual to have pies and a pot of tea sent in from the nearest restaurant about 11 p.m. and when we were more than usually sleepy Dr. Robert Forrest brought out a bottle of a weird mixture labeled 'kid-reviver' and gave us a dose all round to keep us awake.

One line of research was the use of nascent chlorine and bromine, and at this time we had the usual text-book idea that there was "no simple solvent for gold"—a vague statement that served to confuse the mind and lead it away from the fact that mixtures of the *aqua regia* type were only devices for the production of a simple solvent, for example, chlorine. Mr. Morton, our commercial partner, one day innocently suggested that we might find a simple solution to act as solvent. I glibly gave the text-book answer that noble metals were not attacked by simple solvents. Instantly I mentally rebuked myself for giving such a feeble reply, and cyanide was entered on our list as a possibility. Again, I should say that we were little concerned as to the action of any solvent on gold itself, and I do not know that we ever tried our solvents on gold, though we did recognize that anything that would extract gold from ores would dissolve the metal, but not the reverse. It was common knowledge that *aqua regia* would dissolve gold, but that did not take us far, for every gold ore contains a small proportion of pyrite or other sulphide, which instantly precipitates the gold from its chloride solution. If the ore is oxidized by roasting, the precipitation does not occur, but we wanted a simple cheap process, and roasting is neither simple nor cheap. This throwing back of the gold (I hardly dare to call it re-precipitation, though 're' does mean 'back' as well as 'again') by pyrite is common to all acidic solvents. To state it in other words: all acid solvents act first on base sulphides and if by a fluke gold does happen to be dissolved the sulphides do their work and throw it back. This is the nature of the action described in my former note in reference to the recovery of gold from cupreous tower-liquors where CuS precipitates gold from the chloride solution. A solvent to be available for the extraction of gold from ores must be able not only to dissolve it but to hold it against all comers. Cyanide does this, and, so far as is known, it is the only solvent that can do it. This is the real essence of the invention—the matter of weak or strong solutions follows as a matter of chemical (and commercial) economies. It was a great step to find that cyanide of any strength would act thus, and a much smaller step to find that a weak solution was all-round better chemically (and commercially) than a strong one. Certainly the use of zinc as a precipitant was the copestone of the invention, but in itself it was a small affair. We knew that if we could dissolve the gold we could easily find a precipitant. It was common knowledge that zinc would precipitate gold from its cyanide solution and it required no great mental effort to arrive at the conclusion that finely-divided zinc, because if its greater relative surface, would act better than massive zinc. It took us months to arrive at cyanide, but zinc was settled (mentally) in five minutes. The zinc position was neatly put by the Examiner of Patents, the late F. P. MacLean at Washington, when I was trying to persuade him to pass our zinc claim from the process standpoint: he looked at the drawing of the zinc extractor and said "That's not a process, that's a thing."



PRESCRIPTION FOR THE KID-REVIVER.

*Extracts from a recent letter to the Editor.

Some interesting results are being obtained from a tube-mill in the O'Brien mill at Cobalt. This machine is 16 by 6 ft. One 6-ft. section of this has been partitioned off and crushing is done in it with cast-iron balls. The partition consists of a diaphragm separating the load of balls from the load of pebbles beyond it. It has been found to work satisfactorily. It requires more power, but the increased tonnage more than compensates for that additional cost. It has been roughly computed that it requires 15 hp. more to drive it, but there is a 30% increase in the quantity reduced. Another interesting result is that there is a wastage of 4 lb. of pebbles per ton ground, against 1.75 lb. of balls per ton ground.—*Northern Miner.*

Mining at the Nevada Consolidated

By P. B. McDonald

Comparatively little has been written about the mines of the Nevada Consolidated Copper Co. During the nine years that the company has operated, the best reading of what has been done is contained in the statements of the president and consulting engineer as published in the annual reports to the stockholders. These reports have chronicled the cost of mining by steam-shovel in open pits, and the amount of ore in reserve after each year's extraction. The ore reserve has always been a critical factor, and has militated against buying of the stock as an 'investment,' as was widely done with Utah Copper shares. In 1906, when Mark L. Requa delivered his address at the driving of the last spike of the Nevada Northern railway, which bridges the 150 miles from the mines and smelter of the Nevada Consolidated near Ely to the main lines of railway to the north, he said, "to justify the building of the railroad required the development of millions of tons of ore; I think you will agree with me that we are justified when I say that there is developed at Copper Flat and at Ruth sufficient ore to supply the reduction plant for at least ten years." At that time the assured ore was computed at 14,432,962 tons averaging 1.97% copper. Since the beginning of operations to the present time the company has produced and sold 400,000,000 lb. of copper, yet the recoverable developed ore on December 31 last was estimated at 50,525,289 tons of 1.652% copper, assuring a life of at least 15 more years. That is, at the end of the mine's allotted 10 years of life, after producing a good deal more copper than had been estimated, there still remains an ore reserve more than three times larger than the orebody as originally limited.

As is seen by the accompanying table of yearly ore estimates, the company is in the best position since its inception.

	Tons	Copper %
Sept. 30, 1907	14,432,962	1.97
Sept. 30, 1908	20,000,000	1.94
Sept. 30, 1909	29,000,000	1.94
Sept. 30, 1910	40,360,823	1.70
Dec. 31, 1911	40,853,371	1.66
Dec. 31, 1912	38,853,551	1.67
Dec. 31, 1913	39,108,590	1.65
Dec. 31, 1914	41,020,296	1.68
Dec. 31, 1915	50,525,289	1.652

The following general considerations can be stated: a great deal more ore has been proved available than was at first estimated; the grade of ore has been somewhat lower than was anticipated; although many economies and improvements have been effected by the operating staff, the proportion of copper recovered from the ore has been less than 70%. However, it is quite evident that the judgment of F. W. Bradley, J. H. Mackenzie, and Mark L. Requa, who developed the enterprise, of J. Parke Channing, who interested capital in it, and of Pope Yeatman and C. B. Lakeman, who have directed its management, have been splendidly vindicated.

Regarding the low proportion of extraction, it was remarked recently by a pessimistic critic* that the companies operating the 'porphyry copper' mines of the West have nothing in particular of which to be proud. He argued that "an enormous quantity of cupriferous material is rushed through mills, and sufficient copper is caught to pay temporary dividends. The copper has been taken out and sold, largely to foreigners, at an alleged profit of from two to three cents per pound, and in doing this nearly two pounds of copper have been wasted for every three pounds recovered." It can be stated, in answer to this, that the proportion of copper recovered at the disseminated copper mines is now being decidedly increased. This is a result of the introduction of operating economies by the staffs at the reduction works, and of the saving grace of the new metallurgical aid, flotation. In the figures quoted by Mr. Austin in the above criticism of 'big business' he gave the recovery of copper at the Nevada Consolidated in 1912 as 66%; this has been increased to 70.18% for 1915 and probably will be improved further for 1916, when the refinements of the flotation process have been adjusted. To illustrate the bettered copper recovery of the porphyry mines, the Inspiration mine made a 79.95% recovery in 1915, the Miami 75.17%, while Utah Copper, Ray, and Chino, the recoveries of which ran from 50.6 to 57.4% in 1910-'11-'12, rose to 66.04, 67.88, and 67.86% in 1914. Still higher recoveries are possible, but not profitable, at this time; however, the flotation process is bound to raise the proportion recovered—some authorities predict as much as 10%.

Nevada Consolidated compares with the other porphyry coppers as follows, the figures being for operations in 1915: the grade of ore mined, 1.54% copper, was the lowest of any of the six companies except the Utah Copper, which was 1.434%, Chino and Miami being highest with 2.155 and 2.17% respectively. As to size of output Chino, Ray, and Nevada Consolidated each produced between 62,000,000 and 69,000,000 lb. of copper. The Nevada Consolidated mined the largest tonnage of ore, 3,081,520 tons, except Utah Copper, which mined 8,494,300 tons; these figures compare well with those of the Mesabi range iron mines. The Nevada Consolidated paid the largest amount in dividends, $2,999,185, next to Utah Copper's $6,904,082.

It is interesting to note, as pointed out by the financial

*W. L. Austin on 'Big Business,' M. & S. P., July 24, 1915.

press, that the shares of the porphyry copper mines have not attracted the same sentimental interest in trading on the stock exchanges, in proportion to their dividends, as, for instance, the Anaconda. Either the great disseminated orebodies, mostly worked by steam-shovels in open pits, do not appeal to the share-buying public to the same extent as the Michigan or Montana coppers, or perhaps the personality of the controlling interests of the porphyries does not inspire the same confidence as those concerned with the mines at Butte, Bisbee, or Calumet. Of course, the predictions of 10 years ago that the porphyry coppers would swamp the market with 5-cent copper did not materialize. In 1915 their total cost per pound of putting electrolytic copper on the Atlantic seaboard varied from 7.12c. in the case of Chino to 9.42c. for Ray, with Nevada Consolidated at 8.23c. and Utah Copper at 7.48c. These costs include "all possible charges, such as shipping, refining, marketing, legal expense, taxes, plant, and depreciation charges." The personnel of the boards of directors of the six porphyry coppers is a matter of general interest. It is as follows:

Utah Copper Co.: C. M. MacNeill, president, D. C. Jackling, managing director, Charles Hayden, Spencer Penrose, K. R. Babbitt, Murry Guggenheim, S. R. Guggenheim, S. W. Eccles, William Loeb, Jr., W. Hinckle Smith, John Hays Hammond, Wm. B. Thompson, Frank A. Schirmer, Eugene Meyer, Jr., Kenneth K. McLaren.

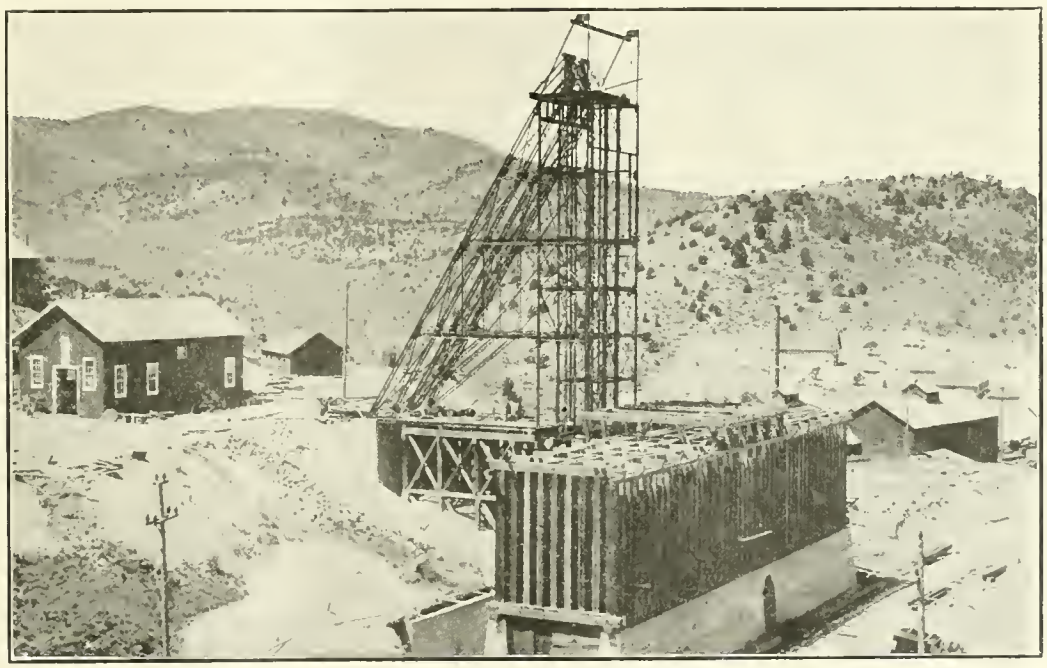
Nevada Consolidated Copper Co.: S. W. Eccles, president, D. C. Jackling, vice-president, C. M. MacNeill, Murry Guggenheim, S. R. Guggenheim, Judd Stewart, W. Hinckle Smith, Charles Hayden, W. E. Bennett, J. N. Steele, Wm. B. Thompson.

Ray Consolidated Copper Co.: Sherwood Aldrich, president, D. C. Jackling, managing director, A. Chester Beatty, Charles Hayden, C. M. MacNeill, Seeley W. Mudd, Spencer Penrose, E. P. Shove, W. Hinckle Smith.

Chino Copper Co.: C. M. MacNeill, president, D. C. Jackling, managing director, Charles Hayden, K. R. Babbitt, A. Chester Beatty, Sherwood Aldrich, Mark L. Sperry, Arthur J. Ronaghan, W. Hinckle Smith.

Inspiration Consolidated Copper Co.: William B. Thompson, president, Joseph W. Allen, John F. Alvord, Thomas F. Cole, Edmund C. Converse, William E. Corey, Charles A. Corliss, Philip L. Foster, Eugene Meyer, Jr., Louis D. Ricketts, William G. Rockefeller, John D. Ryan, Charles H. Sabin, William B. Thompson, William D. Thornton, Albert H. Wiggin.

Miami Copper Co.: Adolph Lewisohn, president, J. Parke Channing, vice-president, J. H. Susmann, Sam A. Lewisohn, Theo. L. Herrmann, B. Hochschild, William H. Nichols, Walter T. Rosin, F. W. Estabrook, Hermann Sieleken.



THE RUTH MINE OF NEVADA CONSOLIDATED, AT RUTH, NEVADA.

In the way of practical mining, the Nevada Consolidated is somewhat different from the other porphyries. An important bearing upon its mining methods is occasioned by the comparative softness of the orebodies as compared, for instance, with the harder ore of the Ray mine. Again, the copper is found more uniformly disseminated through the ore, unlike the bunchy aggregates of copper sulphide in the Utah Copper monzonite. The large amount of iron sulphide has always been a troublesome difficulty in the concentrating. This has reacted against the efficient concentration of the ore at the mill. Regarding this, the consulting engineer, Pope Yeatman, said in his last report: "the average per cent copper contained in the concentrates was appreciably greater in 1915 than in 1914, being 6.14% in 1914 and 7.77% in 1915." Even this figure, 7.77%, is evidently very low, contrasting with 41.91% at Miami and 32.67% at Inspiration. However, Nevada Consolidated is the only

ores of the six porphyry mines that smelts its own ore so its low grade concentrate is less of a disadvantage.

The Nevada Consolidated has been an open-cut mine worked by steam-shovels. But during recent months the mining of the Ruth orebody, which is a half mile from the pits, has been started by underground methods, and the 14,000,000 tons there will be extracted by a modified 'caving' system. By reason of the deeper overburden on this orebody, it was estimated that the cost of stripping and working by pits would be greater than by underground methods. The ore at the Ruth is of comparatively high grade, being 2.35% in copper.

The starting of underground mining at a mine where open-pit work has been the practice attracts a different set of men. Surface work is largely a problem in rough and ready railroading. The qualities necessary in the employees are forceful 'get-there' leadership, some skilled mechanics, and a gang of common laborers. At the underground mine a different note predominates, and the individualistic characteristics that distinguish underground metal-miners are apparent in the faces seen. The large proportion of young men at the Ruth mine is especially noticeable. The decision to extract the Ruth orebody by underground mining, rather than by pits and steam-shovel, gives point to the opinion of some engineers who think that if the Utah Copper Co. were to open its mine anew, it would be done by underground mining because of the higher cost of the pit work than had been estimated.

It is scarcely fair to compare the mining costs of mines in different stages of their history, but for an approximate comparison the following figures are interesting. The mining cost at the Nevada Consolidated in 1915, practically all from open pits, was 15.24c.; added to this is a 'redemption cost' for the removal of overburden, varying from 15 to 30c. per ton of ore at the three pits of the company. At the Utah Copper, where open-pit work by steam-shovel accounted for practically all the ore produced in 1915, the cost of mining was 24.41c. per ton, of which 7.50c. represents charges for stripping. At Chino, also open-pit, the cost of mining ore in 1915 was 19.47c.; the charge for stripping is not given. At Ray Consolidated, where underground mining is done, the cost of mining in 1915 was 58.97c. per ton; which includes all fixed and general charges. At Inspiration, an underground mine, the mining cost for 1915 was 68c. per ton, which includes 20c. per ton of calculated charge for development by drifts, raises, and haulage-ways. At Miami, an underground mine, the mining cost in 1915 was $1.01 per ton, of which 31c. was for development and 70c. for mining.

The Ruth orebody is a nearly flat slightly-dipping wedge or lens, several hundreds of feet in length and width, and about 125 ft. thick on average. The greatest depth of ore from surface is 500 ft. In many ways this mass of soft copper ore is similar to the iron deposits of the Mesabi range, and the problems incident to its economical extraction are nearly identical. A difference lies in the fact that this copper mine is dry, as compared with the torrents of water that compleate underground mining in Minnesota. A vertical shaft has been sunk in rock several hundreds of feet from the orebody and the levels marked off by drifts at regular intervals.

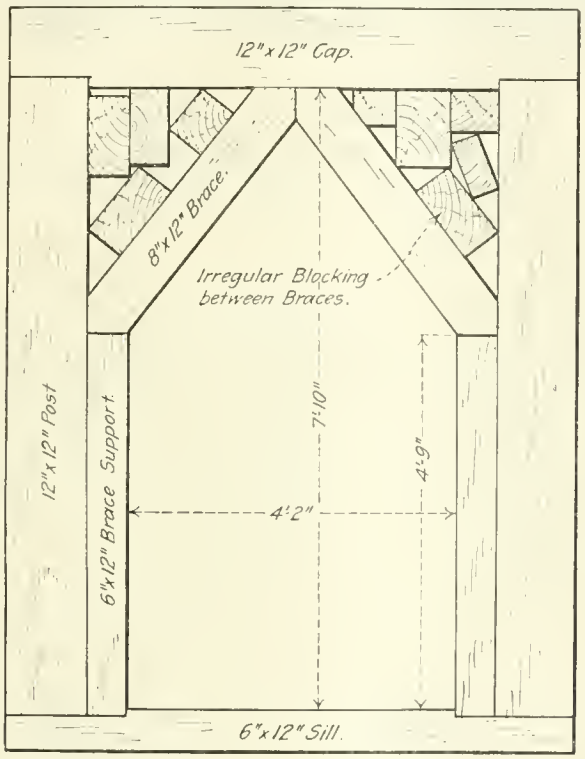
The stoping is done by a combination of the Ray system of room and pillar mining, by shrinkage and caving, with a branched raise method on the lower levels. The Ray system is more suitable for hard ore, so it has been found advisable to employ it at Ruth only in a modified way. The general principle of the Ray method, it will be recalled, is to over hand stope a number of comparatively small shrinkage-rooms, with pillars of ore between, which are later extracted by caving; the idea being that it is easier to cave the orebody in a checker-board of small operations, where the work can be watched and directed carefully, than to engage in a wholesale method such as block-caving. Incidentally, the worth of the system of stoping at Ray was questioned by Professor F. W. Sperr in a recent article† on stoping methods, when he suggested that block-caving might have found excellent adaptation there. Above the 300-ft. level in the Ruth mine, caving by the Ray method has been generally applied. A good deal of difficulty was encountered in holding up drifts in such soft ground, where heavy angle-braced timbering only lasts a few weeks before it becomes crushed. The character of this orebody is not unlike that of an old compacted stock-pile; it is crumbly and broken to an extreme degree. Below the 300-ft. level, inclined raises have been put up from the 500-ft. or main tramming level. From these raises, branches are extended near the top, so that eight branches, at 12½-ft. centres at their tops, feed into one loading-chute. All raises are inclined, because the ore runs better, not blocking itself as it would in vertical raises. The long main raises are on a 50 or 60° incline, the short branched raises are 45°. Careful surveying is necessary to bring the tops of the raises at the properly spaced interval, 12½-ft. centres, so that practically no shoveling or wheelbarrowing of ore need be done. All raises are timbered closely with heavy squared timbers (not the ordinary loose cribbing)—a considerable item of expense. As regards this method of stoping by branched raises, the following is quoted from a recent article on 'Mining by Branched Raises' by F. W. Sperr:‡ "Soft ore has a greater tendency to pack in chutes at a high angle, as well as to hang up in chutes at lower angles. The best angle for the worst ores is 65°, but some ores run freely at 45°. With hard ore, not so much trouble is experienced from packing in vertical raises; therefore the raises are made vertical in places for convenience of arrangement. Accessibility to the vertical chutes for the purpose of relieving the tendency to pack, can be more readily provided where the branches are inclined throughout their entire length, than in the case where they are partly vertical."

Robert Marsh, Jr., the general mine superintendent of the Nevada Consolidated, summed up the advantages

†M. & S. P., February 19, 1916.

‡M. & S. P., May 20, 1916.

and disadvantages of mining such a soft heavy orebody by saying: "It is economical in powder and air, but it is necessary to count on the ground falling wherever it has any chance; it is not uncertain ground, for it will always fall; the caving of the overburden must be done according to some regular plan, or it will get mixed with the ore; it can be caved along a horizontal plane or on a slope, but care must be taken not to cave tongues of overburden into the ore." A recent incident at the mine was the raising of a 500-ft. incline from the tramming-level to surface, in order to get a small stock-pile of ore that was extracted in sinking an old incline shaft. This stock-pile could not be reached handily by teams on surface, as it lay over a ridge of rough ground. It will be taken down the long raise, trammed to the shaft, and hoisted in the usual way.



ANGLE-BRACED TIMBERING IN THE RUTH MINE, WHICH BECOMES CRUSHED IN A FEW WEEKS.

The rock-drilling practice is somewhat different from that of a hard-ore mine. Seven or eight 6-ft. holes are employed in driving, making 45 ft. of drilling per cut. A record of fast driving was made in the development of the mine when 476 ft. was achieved in one month by two miners (one per shift) and four trammers, a total of six men. A light mounted one-man drill was used. But, after making this whirlwind record, the type of drill was found not adapted to this soft ore, and has been discarded. It was not that the rock was too hard for the drill, but that it was too soft. Being designed for a harder rock, the parts of the drill were too strong for this work and quickly wore themselves out by getting stuck in the soft rock and breaking the rotating device.

The mounted hammer-drill is well liked here. This is interesting, as such a type of drill is not supposed to be at its best in soft rock, because clayey cuttings are apt to choke the circulation of water. The mounted hammer-drill, such as the Leyner, is generally best in medium-hard rock, but in this mine the ore, while soft, is not clayey. As to stoper drills, the underground foreman remarked that he had tried thoroughly the products of two well-known manufacturers. Both did good work at the start, but one wore much better than the other, so he is putting in that type. Robert Marsh, the general mine superintendent, had a word to say about too many automatic devices on rock-drills. "They are likely to be valuable only for salemen's arguments," he remarked.

A mechanical ore-loader of the Halby type is being tried underground at the Ruth mine; it is too early to say if it will be a success. This machine loads tram-cars in drifts by electric power; it is manufactured at Marquette, Michigan. No candles are allowed in the Ruth mine, on account of fear of fire in the dry timbering. Carbide lamps are used with good satisfaction. The problem of giving the men what they want in their dinner-pails, so that individual taste is provided for, is solved by a modified 'cafeteria' arrangement. The men walk along where the foods are served, and each one's lunch is put up according to his preference. Such consideration for the men is well advised; good food promotes effective work.

At the pits, the operation of getting loaded cars out and empty cars in: of efficient steam-shoveling; and of drilling and blasting, have been perfected to an admirable degree under the direction of E. E. Vanderhoef. Churn-drills, or 'well-drillers,' of the Keystone type are employed to drill 6-in. vertical holes along the benches, usually to 30 or 50 ft. depth. These holes are put down 5 ft. deeper than the bench-level below, to make sure that the steam-shovels will not have to dig in unbroken rock. An iron funnel and long canvas hose are used to facilitate dropping the 'sticks' or cylinders of dynamite in the holes. Several kinds of dynamite and black powder are used as the various types of blasting may require. The holes are sprung or enlarged several times before being filled with explosives. Drift-blasting is only occasionally considered necessary. The 'well-drillers' give excellent results and appear adapted both for mining of the soft ore and for the stripping of overburden. These machines are used also to churn-drill to a depth of 500 ft. for exploring the orebody in advance of the mining. They are moved on their own wheels, but at times are transported on railroad-cars for longer distances. At the copper mines at Chuquicamata, Chile, where the ore is much harder, the churn-drills for blasting are said to have been superseded by tunnel-blasting, the 'tunnels' being driven by hand. We shall have some notes on this shortly from Howard W. Moore, with drawings showing how the tunnels are loaded.

The Nevada Consolidated is on the Lincoln highway, which extends from New York to San Francisco. A sign-board on a rather indifferent piece of road in front of the mine, in the midst of mountain peaks and sage-brush flats, is labelled 'to New York.'

Mining in Sardinia

By O. C. Engelder

The north end of Sardinia is due west of, and 110 miles from Rome. The island is 150 by 60 miles, with an area of 9187 square miles, exceeding that of Massachusetts. Steamers depart from Civitavecchia, a port 50 miles from Rome, every evening and arrive at the north end of the island early the next morning, where connection is made with the railway. An American tourist in Europe, with an eye for scenery, would be well repaid to give Sardinia a few days. The roads, hewn from solid rock and kept in perfect condition by the Government, fulfill all the demands of the motorist. Villages of one to five thousand inhabitants are scattered over the mountain slopes. The low buildings of stone and adobe with their whitewashed walls and red-tile roofs, and the curved and cobbled streets, are in accordance with customs that have not changed for centuries. Cagliari, with its 60,000 inhabitants, is the chief city.

The lead-zinc mining district is in the south-west. It is impossible to tell when the first lead ore was mined, since the civilization of this island dates back to prehistoric days. From relics found in old mines, such as bronze tools, lamps, stone picks, jasper hammers, lead slabs with dates cast in them, and from ancient tombs and mounds, it is known that the mining was done by the Phoenicians, Egyptians, Carthaginians, and finally the Romans. Until 1865, lead with its silver content was the only ore mined; this consisted of galena and cerussite. It was discovered then that much of the material discarded as waste was calamine, the silicate of zinc. From that time the mines of Sardinia have supplied much of Europe's lead and zinc, especially the latter.

Both the carbonates and sulphides of lead and zinc are mined in veins traversing schist, or in limestone at its contact with the schist, or in granite. The ore-shoots are irregular, but fairly persistent in depth. Until four years ago all drilling was by hand. Since then power-drills have been replacing the 'single-jack,' on the initiative of Charles W. Wright, resident manager for the Pertusola company. Many of the operators, however, are slow to appreciate the advantages of machinery. Practically all development is by adit, there being no large hoisting-plants. A power-plant was completed during the past year and the more important mines will soon be operated by electric power.

The ore is concentrated near the mines. Water is abundant. The milling practice is much the same as in the United States. Hand-sorting receives much attention on account of cheapness of labor. Jaw-crushers, rolls, trommels, shaking-screens, jigs, etc., are of the usual pattern. The Wright table is replacing concentrators of an older type. No mills have as yet installed the flotation process, but several are experimenting with it. The chief loss has been in the slime, and since the ores are not complex, flotation should prove helpful.

The total lead concentrate production of Italy in 1913 was 44,651 metric tons, of which Sardinia produced 43,544 tons. The corresponding figures for zinc concentrate were 158,278 and 140,115 tons. The average grade of the lead concentrate was 56.26% lead, and 11.4 oz. silver per ton. The zinc concentrate averaged 40.26% zinc. Also 501 tons of mixed lead-silver concentrate was produced, or a total of 203,436 tons of concentrates valued at $5,621,000. Detailed statistics for the last two years are not yet available. Production during that period, however, has been curtailed by the War. Zinc mining was suspended with the first declaration of war, since practically all the concentrate was smelted in Belgium and Germany. Lately a limited amount of blende has been sold, and one calamine producer is shipping to the United States. The Pertusola company owns its own lead smelter, near Spezzia, and is accepting concentrate from some of the other producers.

No definite scale of wages for miners and shovelers exists. Employees are paid according to ability and the time served with the company. This method has its advantages, but also some disadvantages. To pay for labor according to quality and quantity is the ideal method, but a man's opinion of himself never agrees with the foreman's opinion, consequently there ensues some dissatisfaction. Efficient labor is not plentiful, and the companies are bound to have a large proportion of inefficient men on their payroll. Skilled labor is paid 70 to 90 cents per day, ordinary labor 40 to 60c., helpers and apprentices 30c. up. The best miners draw 50 to 70c. per eight-hour shift; ordinary labor is paid 40 to 60c., and boys 25c. up. In the mills, and where ore is sorted on surface, many boys are employed at a rate as low as 20c. For this work girls also are employed, receiving 15 to 25c. Mill and mine foremen receive $35 to $40 per month. Assayers, shift-bosses, office-men, etc., receive $25 to $40. These wages are low, and so is the efficiency. The men, especially common labor, are ignorant, slow and not healthy, consequently not strong. They are satisfied to live in an easy-going way; to earn enough for daily needs and to exert themselves as little as possible.

The mining laws, strictly enforced by the Government, are in favor of the laborer. One regulation that causes inconveniences to the companies and works against the cost-sheet compels employers to notify an employee a week in advance before suspending him. The employee, also, must give the company the same notice if he intends to quit. It means the company must pay the employee a week's wages when suspending him. Salaried employees must receive three months' notice. If an employee has a grievance, he reports the same to the nearest deputy, who appears at the mine-office in behalf of the employee in a few hours. Mines and mills are not permitted to operate on Sunday unless there has been a holiday during the week. No brothers are allowed to work in the same mine at the same time. Labor unions are unknown, so that the companies are not bothered with strikes.

TOPOGRAPHY OF THE JUDITH MOUNTAINS, MONTANA.

Gold Mining in the Judith Mountains, Montana

By O. W. Freeman

INTRODUCTION. On the plains of Montana east of the continental divide rise several detached smaller mountain groups. Mineral deposits are found in most of them. Since 1880 the Judith mountains have been producing gold and minor amounts of other metals. This group rises abruptly from the plains in central Montana to an average height of 6000 ft., or about 2000 ft. above the rolling plains around them. Judith peak, 6386 ft. altitude, is the highest point.

These mountains consist of several detached peaks connected by ridges, and run in general north-east. Weed and Pirsson first showed (18th Annual Report U. S. G. S. Part 3, Pages 437-616) that these peaks are the result of laccolithic intrusions in post-Cretaceous time. In the case of Judith peak, however, no floor of sedimentary rocks, which is necessary in order to have a laccolith, has been discovered; hence the intrusion is more in the nature of a stock. The outcrop of this stock is four miles across. More differentiation could occur in this large mass of igneous rock than in the smaller laccoliths, and therefore the richest gold deposits are found in its vicinity. The laccoliths are chiefly composed of rhyolite-porphyry, but some granite and syenite are found. Later dikes and sheets of phonolite-porphyry intrude both the rhyolite and sedimentary rocks. Mineral deposits are found associated with intrusions of both periods. Small amounts of gold and other metals have been detected, by assay, in the intrusive rocks, and there is no question but that the mineral deposits were derived from the molten magma.

GEOLOGY. No pre-Cambrian rocks are found in the Judith mountains as in the near-by Little Rockies and Little Belts, but there occurs a complete and apparently conformable series of Paleozoic rocks ranging in age from the Cambrian to late Carboniferous. Only the top of the Cambrian, which includes shales, conglomerates, and limestones, is exposed, but this is known to be over 500 ft. thick. The rest of the Paleozoic is from 1000 to 1200 ft. thick. The Carboniferous formation in the Judiths is mostly limestone, belonging to the Madison formation of the Lower Carboniferous. At Yogo in the Little Belts 1200 ft. of shale and sandstone overlies the Madison and is known as the Quadrant formation, but in the Judiths this formation appears to be practically absent. Several thousand feet of Jurassic and Cretaceous shales and sandstones once covered what is now the Judith mountains, but erosion has removed these except where protected in synclinal folds between two intrusions as at Ruby Gulch and Maiden. From the tops of the laccoliths erosion has removed from 5000 to 6000 ft. of sedimentary rocks and exposed the intrusive rhyolite-porphyry. The sedimentary rocks dip steeply in all directions away from the laccoliths. Some of the peaks are themselves composed of porphyry, but more often the highest points are ridges of hard limestone, while the valleys between are eroded in the softer porphyry and Cambrian rocks.

A few small veinlets are found in the porphyry; in Alpine gulch west of Maiden these are gold-bearing and in Judith peak east of Maiden they carry lead and copper, but they are small and unimportant. Claims have also been located near the contact of phonolite dikes, but actual gold production has been small. The valuable orebodies are replacement deposits of gold in limestone near the contact with intrusive laccoliths or sheets. The ore deposits usually occur in well defined shoots and chimneys, which sometimes consist of high-grade ore surrounded by low-grade. If the ore is near a sheet of porphyry, it is always underneath the porphyry, which serves as the hanging wall. The richest ore, as at the Spotted Horse mine, is accompanied by purple fluorite. The fluorite resulted from the action of hydrofluoric acid

on limestone. This acid probably was brought by solutions from the intrusive molten magmas and may have aided in dissolving the gold. The gold-bearing limestone of the orebodies is usually siliceous, often jasperoid, and is more crystalline than before mineralization. The chief mineral deposits occur in the Carboniferous limestone, and are usually restricted to the upper part of it. This probably results from the upper Carboniferous limestone being thin-bedded with many crevices that mineral-bearing solutions could follow, while the lower Carboniferous is massive and thick-bedded. The limestone near the intrusions has frequently been brecciated, the angular fragments being cemented and replaced by ore. As the intrusive porphyry cooled, its volume would naturally contract and crevices would open along the contacts with the sedimentary rocks, which would serve for the passage of mineral-bearing solutions. The solutions could more easily dissolve the limestone and replace it with sulphides than the shales and sandstones, therefore little mineralization has occurred except in the limestone. Also carbonaceous matter in the limestone may have helped to precipitate the gold, as would also the lower pressure and temperature in the limestone. The orebodies are chiefly restricted to limestone and porphyry contacts, but occasionally shoots are found to extend some distance into the limestone, and sometimes the porphyry itself has been replaced. The gold seems to have been chiefly deposited as a telluride along with quartz, pyrite, calcite, and fluorite. Since the mineralization happened, erosion has removed the overlying rocks and exposed the mineral deposits. Surface waters and the air have oxidized the pyrite, chiefly to limonite, resulting in staining much of the ore a red, yellow, or brown. Practically all of the ore thus far mined is softened and decomposed by the agents of weathering. Free gold is rarely seen.

The Mines in the Judith mountains require little timber, what is required being cut near-by. A good grade of sub-bituminous coal outcrops in the foot-hills a few miles away. Maiden, the chief town in the Judiths, is situated near the centre of the range and has a population of only a 100. At one time nearly 1000 people lived there. Hilger, on a branch railroad from Lewiston, is ten miles from Maiden and is the nearest railroad point. A daily stage connects with the trains. Lewiston, the county seat of Fergus county, is about 18 miles south-west of Maiden. Placer gold was discovered in Alpine gulch near Maiden in 1880, and quartz claims were located soon afterward. The placers were small and were quickly exhausted, but the production from the quartz mines has been probably $9,000,000.

The most important mines are those near Maiden, and of these the best known is the Spotted Horse, which is the largest producer. This mine was located in 1881 and operated fairly continuously until 1902, when it was closed, not to be re-opened until 1912. Its total production is considerably in excess of $5,000,000. Much of the gold produced during its early operation was from high-grade ore, some being worth $30,000 per ton. The fluorite gold ore shipped to the smelter averaged about $100 per ton. A modern cyanide mill has just been completed and is now in successful operation on the lower grade ore. The mill has a rated capacity of 50 tons, but its actual capacity is more nearly 75 tons. Before the mill was built, no ore worth less than $20 per ton could be shipped profitably to the smelter, now ore as low as $3 per ton can be milled at a profit. The mill is provided with concentrators, the concentrate being shipped to the smelter. The mine is only developed to a depth of 585 ft., but the geologic conditions are such that it is reasonable to expect large orebodies. Enough ore is in reserve to supply the mill for several months. The mine is now producing about $12,000 in gold per month.

The McGinness mine was located about 1880 and was worked at intervals to 1899. It was then closed until 1909, and since then has been worked chiefly by lessees. New machinery is being installed, and the mill is being overhauled. The McGinness has produced nearly $2,000,000 in gold. The mine is developed to a depth of 426 ft. with over a mile of drifts. It is equipped with a 10-stamp mill, a concentrator for high-grade ore, and a cyanide-plant for the low-grade. As at the Spotted Horse much high-grade ore averaging $100 per ton was shipped to the smelter. The ore of both the Spotted Horse and McGinness occurs in the Carboniferous limestone below steeply inclined sheets of porphyry that serve as the hanging wall of the stopes. The richest ore, consisting mostly of quartz and fluorite, is of a purple color.

The Cumberland mine, near the Spotted Horse, has been operated in recent years by lessees. It has produced about $270,000, mostly in gold. It is developed by a 1000-ft. adit, and is equipped with a 150-ton cyanide-plant. The ore is found at the contact of limestone and porphyry. Above the adit the known ore has been removed, but recently the lessees have found ore of milling grade below the adit in a drift from a winze 40 ft. deep. Further development is now in progress.

The War Eagle is near the Cumberland and since 1910 several shipments of zinc ore carrying gold, silver, and lead have been made. The Cave mine on West Armell's creek has also produced lead-silver ore in recent years. On the north side of the Judiths much development work has been done on the Copper King claim, where copper is the principal mineral. Prospecting has also been done on many other claims around Maiden, among which might be mentioned the Mount Grassy group, which has recently been bonded and sampled.

On Elk Mountain at the east end of the range work has been done on a lead-silver claim with encouraging results. The high price of the base metals has encouraged prospecting and work is active on several properties that ordinarily it would not pay to operate.

The Gilt Edge mine is on the east side of the mountains south of Maiden. The town is practically deserted today, but for several years following 1898 the neighbor-

ing mines were the most productive of any in the district. Their production is probably not far from $1,500,000. The ore is low-grade, but a high recovery can be obtained cheaply by cyanidation. These mines were located in 1884 and '85. The orebodies occur under an intrusive sheet of porphyry in the soft thin-bedded Upper Carboniferous limestone. The 300-ton cyanide mill at Gilt Edge produced $1,250,000 in gold from ores that came mostly from the Gold Reef and Great Northern properties. The mill was dismantled a few years ago and the production since then has been small, although a little gold-silver ore has been shipped from time to time.

The Whiskey Gulch mine has a 100-ton cyanide-mill and produced $165,700 in 1903-'04 from $5.50 gold ore, but has been closed since, on account of friction between stockholders. It is claimed that a large amount of low-grade ore is developed. The Mammouth near-by also has a 100-ton cyanide-plant and ore developed that will average $6 per ton, but production has been small and it has been closed for several years owing to disagreement between the owners. A lease has been taken on the Whiskey Gulch mine and it is hoped that both of these properties will be re-opened soon.

The New Year mine is on the north side of the range west of Maiden. Several claims were located in New Year gulch in the early '80s, but although much money has been spent on development work the production has been small. As at Gilt Edge the orebodies occur in limestone under sheets of porphyry. The New Year itself is now idle, development work having failed to disclose any large orebodies. The New Year mill was re-built in 1911, and is of 150-ton capacity. Development work is now being done on the Gold Acres claims adjoining the New Year property. An adit 800-ft. long has been driven and work is progressing in drifts and raises. It is said that ore worth $4 per ton has been developed. It is planned to treat this ore at the New Year mill, and if development continues favorable to construct a large cyanide-plant. Among the other prospects located near New Year are the claims of Finlaw and Allister, who have found ore suitable for cyanidation.

Outlook. Besides the mines and prospects mentioned, work is being done on others, several of which have produced some gold, such as the old Florence mine. The total production of metals from the district, chiefly in gold, is estimated at from $9,000,000 to $10,000,000. Unfortunately, development has rarely preceded extraction, and usually has been of a haphazard character. Frequently when the ore in sight was exhausted the mine was abandoned. There is little doubt but that careful prospecting and development will disclose large bodies of low-grade cheaply-mined gold ore, and possibly some deposits of the base metals will prove valuable. Mining has been at a low ebb in these mountains for several years, the output in 1914 being only $100,810, mostly in gold. Recently several old properties have been re-opened and other new properties have entered the list of producers. The high price of metals has stimulated prospecting, and the outlook is the best for many years.

Sulphuric-acid production of the United States during 1915, expressed in terms of 50°B., amounted to 3,868,152 short tons, valued at $29,869,080. The average price was $7.72 per ton, according to the U. S. Geological Survey. The 66° acid sold for $13.95 per ton. By-product acid was as follows:

Source	Quantity	Value	Price per ton
Copper smelters, 60°	360,522	$2,749,633	$7.63
Zinc smelters, 60°	484,942	4,292,493	8.85
Other strengths	59,189	579,115	9.78
Total	904,653	$7,621,241	$8.42
60° acid reduced to 50°B.	1,056,830		

Too much weight must not be attached to the values given in the tables, as prices varied widely during the year. Producers who had previously entered into long-time contracts sold acid at prices much below those now current, especially during the last part of 1915. The trade in strong acids was active on account of the demand from the explosives and war munitions' industries, but this demand came only after the first quarter of the year and was very strong only during the last half. Before that time some acid plants were shut-down. The average values given are therefore much below those which ruled on the market at the close of the year. In 1914 the output of acid, reduced to 50°B., was 3,762,417 tons valued at $24,163,331, or $6.42 per ton. Of this, 950,798 tons was recovered from copper and zinc smelters.

Erzerum, the city in Armenia recently captured by the Russians, has long been an important trade centre. It is 110 miles south-east of Trebizond on the Black sea, on a fertile plateau 6000 ft. above sea-level. Snow-clad mountain peaks surround the city and the climate is severe, the winters being long and cold. One of the principal industries is the working of copper, iron, and brass. It will be recalled that in Turkish countries, a man's wealth is indicated by his stock of copper vessels, which are prized highly. Erzerum is a settlement of great antiquity, having been founded by one of the early Roman emperors. It is on the caravan route from Trebizond to Teheran, and from Teheran to Mecca—a much traveled pilgrimage for Mohammedans. The importance of the caravan routes has declined somewhat since the building of the trans-Caucasian railway.

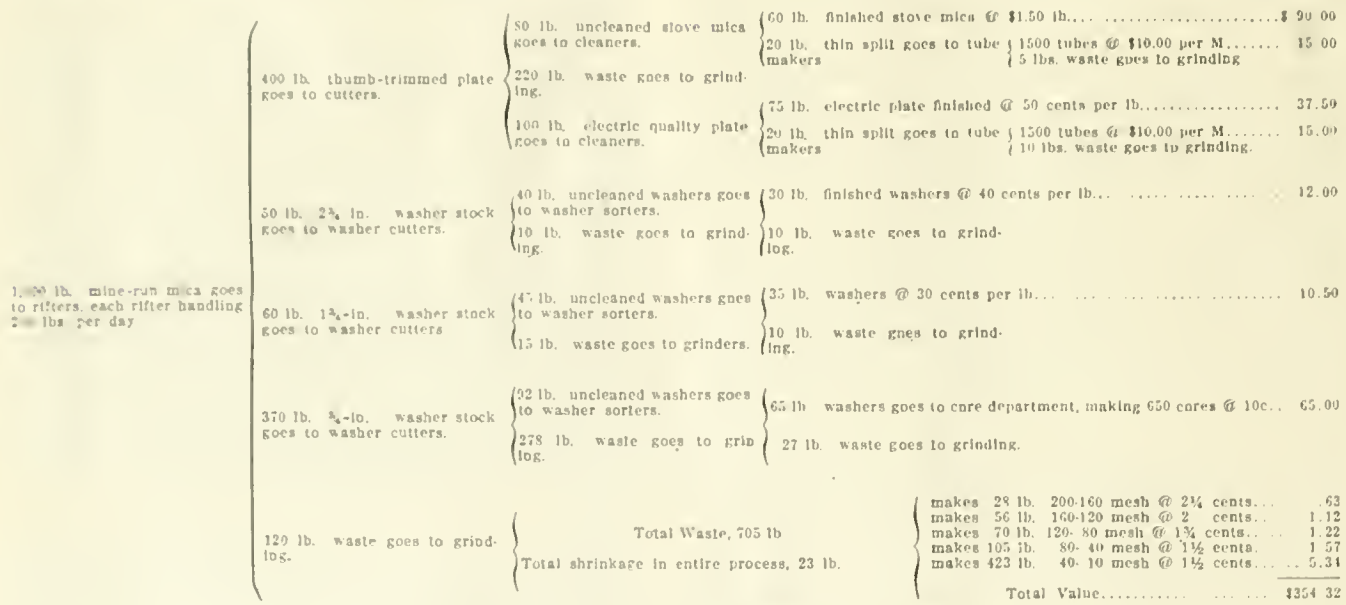
The Compañia Real del Monte of Pachuca, Hidalgo, Mexico, is, perhaps, the largest producer of silver in the world. It operates in normal times eight silver mines about 70 miles north-east of Mexico City. The company is a subsidiary of the United States Smelting, Refining & Mining Co. of Boston. The Anaconda company at Butte, produces nearly as much silver as the Real del Monte, the silver being a by-product of its copper output.

Mica Mining

A number of enquiries have come in to us as to the practicability of mining mica in the Western States. At several metal mines a good deal of mica in fairly large crystals has been noticed, and the question has been asked as to whether it is worth while to sort out the mica and try to market it. At the start it can be stated that the marketing of mica, like that of the other secondary minerals, is a business not easy to arrange on a satisfactory basis. This is due to the fact that the marketable qualities of many non-metallic minerals vary so greatly that a consumer who has been obtaining his supply from a particular source, which has proved fairly satisfactory, is loath to buy from a new producer, because, even if the quality of the material seems good at first, he is not sure that future lots will continue so. Government publications, and those of various State departments, contain a lot of statistics of production and imports of mica, but information of the sort that the miner wants is scarce. In fact, the essential knowledge of how to prepare and market many of the non-metallic minerals is held only by individuals actually engaged in the business. Some consulting engineers make a specialty of non-metallic and minor minerals, and their advice should be secured in preference to spending much money on a plant or development, if the operator is in the dark as to the conditions of the trade. The companies that deal in unusual ores will generally buy odd lots of miscellaneous minerals if they can inspect them in advance and determine that they are valuable.

London has always been an important market for mica, and the products from India, Canada, Africa, and Brazil are brought there and sold. Sale is by auction, as this method enables the buyer to see exactly what he is getting. In the United States, the companies manufacturing electrical machinery require more or less mica, but the General Electric Co., for instance, mines its own product in New Hampshire and Ontario. Muscovite, the light-colored tough elastic potash mica, is the only variety of mica mined in this country. North Carolina leads in production; in that State farmers go mica hunting when crops do not require their attention. The deposits of commercial value have been found usually in pegmatite. Quebec is also an important, but irregular, producer.

To prepare mica for market, careful sorting is necessary, followed by splitting in plates $\frac{1}{8}$ in. thick. These plates are trimmed and split further. Rough small mica and the waste from sheet mica are ground fine. Both wet and dry grinding are done, but the methods are kept secret. The average price for sheet mica in this country during 1913 was 21c. per lb. as compared with 33c. in 1912 and 16c. in 1911, according to the U. S. Geological Survey; in other words, it is about as valuable as copper. Scrap mica was sold in 1913 for $15.50 per ton. The total value of the country's mica production in 1913 was $436,000, the largest annual output recorded. Sheet mica contributed $353,517, the value of 1,700,677 lb.; scrap mica was 5322 tons, valued at $82,543. During the same year, imports of sheet mica into this country were $943,018 compared with $748,973 in 1912. Uses of mica other than for insulators in electrical machinery are for stoves, washers, rings, and tubes. Ground mica is used to some extent as a lubricant; also in paints, as an adulterant in rubber goods, and for various minor industrial purposes. The accompanying flow-sheet of an average run of 1000 lb. of mica from a New Hampshire mica mine is taken from Bulletin 16 of the Arizona State Bureau of Mines.



AVERAGE RECORD FROM A NEW HAMPSHIRE MICA MINE.

FULLER'S EARTH production in 1915 was 47,901 tons, valued at $489,219, an increase of 6920 tons and $85,573 over the 1914 total. Imports decreased to 5536 tons.

Heard in the Bunk-House—III and IV

By W. H. Storms

III

"I'm just after readin' about a couple of fellows that got blowed up with powder," remarked 'Swede' Murphy when the men had quieted down in the bunk-house after supper. "It's a wonder they wouldn't get wise some day."

"A great many men think powder is not dangerous to handle," said the timber-boss. "What were these men doing with the powder?"

"Thawin' it out at an open fire," replied Murphy.

"It is safe enough to thaw powder if you do it right," responded the timber-man. "Hot water is pretty good. Most of the patent thawers and others that are any good use hot water."

"I once knew a pocket-miner that was the craziest man with powder I ever seen," said the miner from Arizona. "Him, and another fellow named Joe something worked once in the same tunnel on separate leases. The old man, Hank Gill, worked in the face of the main tunnel and Joe was putting up a raise at the end of a branch from the main tunnel. Joe was a fine blacksmith, but old Hank was no good at it. He'd over-heat the steel and then plunge it in the slack-tub and when he came to drill, the bits would break like glass. The old man had a pretty good blacksmith outfit and shop near the mouth of the tunnel. Joe had an outfit too, but his was at another mine up on top of the hill quite a long way from the tunnel. So to make it convenient, Joe agreed to sharpen the old man's steel for the use of his shop to sharpen his own. This worked all right. One day Joe quit about half-past eleven to sharpen his tools and get his dinner. He packed his picks and drills to the shop, made a fire in the forge—one of those portable affairs it was—and went to work on the steel. He was nearly through when he heard Hank coming. Hank came into the shop whistling and packing a small powder-box under his arm. In the box was 14 or 15 sticks of dynamite. These he began to take out of the box and lay them around the edge of the forge-fire on the black coals. Joe was most scared to death and says, 'For God's sake, Hank, what you tryin' to do—blow up the shop?'

"'It's froze,' says Hank. 'I want to thaw it out. It won't take long.'

"Joe, having finished his work, only lingered long enough to see Hank pile some coal on the fire, punch it vigorously, and commence to stick his drills in, whistling and working the blower to beat the band all the time. Joe started for his cabin some distance away, after again telling Hank he would blow the whole outfit to hell.

"'Ain't you goin' to sharpen these drills?' called old Hank after him. 'What's the matter of ye—there ain't no danger.'

"By this time Joe was on the run, but he yelled back: 'Run, you old fool, you will blow the whole outfit up.'

"'This powder won't hurt nothin,' Hank yelled in return. 'I eat it every morning for breakfast.'

"Joe went about getting his dinner, wondering how long old Hank would be lucky enough to stay alive. It was about fifteen or twenty minutes later that the entire Jackass Hill region was rocked with a terrific explosion. 'There goes old Hank and the shop,' Joe said aloud to himself. 'What a fool I was not to drive the old idiot out of the shop.'

"He hastened to the door of his cabin and looked in the direction of the blacksmith shop, when he was surprised, almost terrified, to see the old man running toward him from the direction of his own cabin. He was waving his arms wildly as he ran, yelling at the top of his lungs: 'By Gad, it *did* go off—it did go off. Yes sir, I wouldn't a believed it— it *did* go off.'

"'Where were you?' inquired Joe, much relieved to know that old Hank had escaped such a terrible death.

"'Me,' responded Hank; 'Oh, you know I can't sharpen and temper worth a cent, and as I was hungry I thought I would go up to the cabin and get me a bite to eat.'

"'Where did you leave the powder?' inquired Joe.

"'On the forge,' ingenuously replied Hank, 'an' just like you said, the damned stuff *did* go off—I wouldn't a believed it.'

"A visit to the site of the shop showed that a part of one post that had formed a corner of the structure was all that remained. Shop, tools, forge, everything, had vanished. The anvil was found over a hundred feet away, at the foot of the dump. It was uninjured. The forge was blown into shreds, the débris taking the direction of the tunnel, as was shown by numerous slivers of steel sticking in the timber-sets back from the mouth of the tunnel. As the old man said, 'It *did* go off'."

IV

"You was telling the other night, Murphy, about that ghost placer-mining outfit," said the timber-man to 'Swede' Murphy.

"Yes, an' wasn't it a beaut?" responded Murphy.

"It was," replied the timber-man, "but no worse than one I saw down on the Colorado river once, though this was built on different lines."

"Let's have it," put in Jimmy Glee, with a grin of anticipated pleasure, for Jimmy liked to hear about these freak mining outfits, and could tell of some interesting observations of his own.

"This company," said the timber man, "was a big concern, as far as money went, for they had plenty of it and put it out liberally, too. They bought up half a dozen sections or so of gravel beds near the Colorado river 50 miles above Yuma. The best of this gravel lay back 5 miles from the river and 250 to 300 ft. higher than the river. What they called 'gravel' was just the loose small rocks and dirt that came from the rocks under it—not washed smooth at all, but just such stuff as you can see almost anywhere on the desert. All the same there was gold in all of this gravel, and for years the Indians and Mexicans had been working it. They worked in different ways, but they always got some gold. Some of them would dig out a lot of this dry dirt—there wasn't a drop of water anywhere nearer than the river. They'd throw out the biggest rocks, screen the rest of it through about a quarter-mesh sieve, and then dump the fine stuff on a blanket, when two of them would catch hold of it, one on each side of the blanket, and toss the dirt up into the air. The very fine stuff would be blown away by the wind and the heavy part would fall back on the blanket and in this, of course, was the gold. This racket could only be worked on windy days, but that was pretty near any day, and sometimes it blows so hard down there that even the gold would be lost. In later years the Mexicans, and some white men too, took in dry-washing machines and these did pretty well whenever they could find a place that had not already been worked over about half a dozen times. From the very fine stuff the men would pick out the little pebbles and blow out the sand and in that way clean the gold. I expect when this gravel was first discovered they must have done pretty well at the dry-washing business. As the best of the ground had been worked over and over, there wasn't much doing when this outfit bought some ground and got ready to tackle the Basin on a big scale. Surveys were made for pipe-lines and flumes. A big pumping-plant was built along the river and pipe laid up the gulch five miles long. This pipe was 10 inches diameter. The scheme was to pump water from the river five miles up-hill to a reservoir located at a place above the gravel-beds, and then to lay another pipe-line from the reservoir to the head of the flume and just sluice the whole country down into the Colorado river, and get all of the gold left in the gravels in a short time by one big operation. When they came to figure on the cost of a cement reservoir in that place they decided to build a wooden tank instead. The tank was built. It was just about such a tank as you will see around almost any mill and would hold perhaps 3000 or 4000 gallons of water. Just think, Murphy, of running a big hydraulic mine with a 3000-gallon tank at the head of the system."

"Great scheme," laconically responded Murphy.

"When the pipe-line and tank was all finished, the flume built, and the big pumping-engines was ready, they started up and the pumps began to send a steady stream up the long pipe-line towards the great tank at the other end of the line. It worked all right for awhile, but after a bit, when the pressure began to show on the gauges, the engines slacked up. There was not power enough, or something not enough, for only a small stream reached the tank at the upper end of the pipe. There was a misene somewhere.

"They tried it for some time, but could do no good in the way of mining, so the whole business came to an end. The company was in the hole about half a million and concluded to call it a loss and quit. I don't know much about such things, but it seems to me this all might have been figured out beforehand, but very evidently it was not done by competent engineers—'*quien sabe?*' as the greaser says."

"I knew a man once," said the Arizona miner, "that was a jeweler, and pretended to be an assayer too. He used to do assaying—his way—for a dollar when the regular price in that camp was three and a half. He picked up many a dollar from the honest prospector, too, I'm telling you. He used to cook the rock some way with acids and things. He always had something on his little stove—the fumes was enough to drive you out of the place. When he had finished cooking a sample of rock he would wash the pulp in a little porcelain dish, dry the concentrate, which generally was so small that no one could tell what it was without putting it under a high-power microscope, and then pretend to weigh this stuff. He called it the button; and then putting his jeweler's glass in his eye, he would go to the window and look carefully at it for a minute or so, talking to himself in a low tone all the time. Then he would solemnly write out a certificate of assay, stating that the rock went so many dollars in gold or silver, or copper, or whatever he claimed it to be, and take the poor sucker's dollar and invite him to come again. One day I took him a piece of white quartzite full of little black specks of horn-silver. I told him I was hard up and could not afford to waste any money on an assay, but would like to have his opinion as to its value, and then, if he thought it worth while I would have it assayed or not as the case might be. He took the ore to the window as usual, looked at it for some time earnestly and then came back to me and says, 'My friend, it's a piece of sandstone, not worth assaying; keep your money in your pocket and come in again when you find something else'."

"I thanked him for his information, and assured him that I would call again, and then I asked him what the little black specks were. 'Them,' he said, 'is fly specks.' Fly specks—what do you think of that? The piece of ore from which I broke my sample had assayed over 1800 ounces silver per ton, and this old fraud didn't know chloride when he saw it."

"He was as dishonest in his small way," remarked the timber-man, "as some of the big outfits that defraud the public out of thousands."

TWENTY BROKEN CAM-SHAFTS at the Simmer Deep mill on the Rand have been welded, and since worked from 8 to 491 days, with an average use of 100 days.

Flotation-Oils

By O. C. Ralston

*The sudden development of the art of flotation has brought about peculiar conditions in the oil market. A few years ago there was considerable expansion in the wood-distilling industry throughout the South on the hope of selling turpentine at not less than 50 cents per gallon. This hope was never realized and the industry became demoralized owing to excessive production and the efforts of some plants to keep going even at a loss. Pine-oil, which previously has had little sale, is a by-product from this industry and has been found one of the best oils for flotation purposes. At the time of the introduction of the flotation process into the country a stock of pine-oil was for sale at an attractive figure.

This supply of pine-oil and its derivatives has been largely exhausted and we are having to depend upon current production for the present supply. Hence the price has soared, and some of the pine-oil on the market has been adulterated.

During 1915 the principal investigation in connection with the flotation-oils was conducted for the purpose of finding a substitute for pine-oil on account of its cost. Most of the wood-creosotes have proved acceptable and are now being sold at lower prices than the pine-oils. How long this condition will continue is a matter of conjecture. The creosotes have proved to be good preservatives of wood, especially of railroad ties. However, coal-creosotes excel wood-creosotes for preserving timber, so that flotation will probably cause most of the wood-creosote to be diverted from timber preservation.

In view of such a possibility, considerable work has been done to determine whether coal-tar and its creosote derivative could not be successfully used as flotation-oil. In many instances it was possible to do so only after adding a small amount of one of the true wood-oils. There is some difficulty in getting the thick heavy coal-tar to mix well with the pulp, so that it is not the most desirable medium, and for that reason the coal-creosotes have met with more favor. Consequently, most of the gas-plants throughout the country have been able to contract for their output of creosote for some time to come. A similar condition prevails with regard to most of the wood-oils. There has been somewhat of a rush in the mining industry for contracts for these products in order that proposed mills will be assured of being able to operate. When Germany gets into the coal-creosote market again there will doubtless be lower prices for that particular product.

The petroleum men have not been slow to seek the flotation-oil market but their products have not as yet met with much success when used alone. It is possible to mix small amounts of pine-oil or creosote with various petroleum products such as stove-oil and to obtain flotation with some degree of success, but the general tendency of petroleum products is to float both gangue and mineral non-selectively. The petroleum products that have met with the most success are some of the crude oils, such as Texas crude, and especially certain high-sulphur crude petroleums, obtainable in Kansas and in California. Stove-oil has met with some success in the copper-concentrating mills, as copper minerals do not have to be concentrated to the same degree of purity as do the lead and zinc minerals.

One other product that has proved successful has been the kerosene acid sludge from certain of the petroleum refineries. This material is the resultant of the removal of certain impurities with sulphuric acid and often consists of as much as 50% sulphuric acid.

The following is a list of dealers in different oils who have placed on the market various products. A host of these dealers are prepared to supply these products at any time, and of fairly uniform quality. None of them has been able to exactly duplicate their carload shipments, so that the general practice is to test each shipment of oil in a laboratory testing device to determine the proper method of using a given shipment of oil. This non-uniformity of shipments will doubtless vanish when the market becomes steady.

DEALERS IN FLOTATION-OILS

WOOD-OILS

Pine-Oils, Resin-Oils, Wood-Creosotes, Tar-Oils, Turpentines, Etc.

1—Pensacola Tar & Turpentine Co., Gull Point, Fla.
2—General Naval Stores Co., New York.
3—Georgia Pine & Turpentine Co., 158 Perry St., New York.
4—Central Distilling Co., Helena, Ark.
5—United Naval Stores Co., New York.
6—American Tar & Turpentine Co., New Orleans, La.
7—Cleveland Cliffs Iron Co., Cleveland, Ohio.
8—Chesapeake Tar & Rosin Co., Baltimore, Md.
9—Custer City Chemical Co., Custer City, Pa.
10—Yaryan Naval Stores Co. Brunswick, Ga.
11—Hussay & O'Connel, Savannah, Ga.
12—Florida Wood Products Co. Jacksonville, Fla.
13—Oregon Wood Distilling Co., Portland, Ore.
14—National Wood Products Co., Wilmington, N. C.
15—Chapman Manufacturing Co., Savannah, Ga.
16—Spiritine Chemical Co., Wilmington, N. C.

Eucalyptus-Oil

17—Atkins, Kroll & Co., San Francisco, Cal., and other importers.

COAL-TAR, COAL-CREOSOTES, AND AROMATIC HYDROCARBONS

1—The Barrett Co., New York.
2—F. J. Lewis Manufacturing Co., Chicago, Ill.
3—American Creosoting Co., New Orleans, La.
4—American Tar Products Co., Chicago, Ill., and St. Louis, Mo.

*Issued by the U. S. Bureau of Mines.

5—Republic Creosoting Co., Indianapolis, Ind., and Minneapolis, Minn.
6—American Coal Refining Co., Denver, Colo.
7—Numerous municipal and smaller coal-gas plants.
8—Numerous by-product coke-ovens, such as
Pennsylvania Steel Co., Steelton, Pa.
National Tube Co., Benwood, W. Va.
Milwaukee Coke & Gas Co., Milwaukee, Wis.
Pennsylvania Steel Co., Lebanon, Pa.
Solvay Process Co., Syracuse, N. Y.
By-Products Coke Corporation, South Chicago, Ill.
Semet-Solvay Co., Detroit, Mich.
Central Iron & Coal Co., Tuscaloosa, Ala.
New England Gas & Coke Co., Everett, Mass.
Illinois Steel Co., Joliet, Ill.
Maryland Steel Co., Sparrows Point, Md.

VEGETAL OILS

1—Cottonseed oil, etc., Southern Cottonseed Oil Co., New York.
2—Corn oil, Corn Products Co., New York.
3—Palm oil, Peter van Schaack & Co., Chicago, Ill.

ANIMAL OILS (FATTY ACIDS)

1—Oleic acid, Peter van Schaack & Co., Chicago, Ill.
2—Oil flotation grease emulsion, Mohawk Refining Co., Cleveland, Ohio.

PETROLEUM PRODUCTS

Crude, Asphaltum Base

1—California crude:
Union Oil Co., Santa Paula, Cal.
Associated Oil Co., Los Angeles, Cal.
Standard Oil Co., Richmond, Cal.
2—Road oil No. 80, Harris Oil Co., Los Angeles, Cal.

Reconstructed Petroleum Oils

1—Special mineral separator, Continental Oil Co., Salt Lake City, Utah.
2—Solulene and minolene, Star Lubricating Co., Salt Lake City, Utah.

Refined Petroleum Products

1—Stove oil, Standard Oil Co., San Francisco, Cal.
2—Stanolind, etc., Continental Oil Co., Salt Lake City, Utah.
3—Flotation oils, Utah Oil Refining Co., Salt Lake City, Utah.
4—Heavy mineral flotation oils, Geo. P. Jones & Co., St. Louis, Mo.
5—Refinery acid sludge, any refinery.
6—Lubricating oils, any company.

SPECIAL MIXTURES OF MINERAL AND WOOD OILS

1—Calol oils, Standard Oil Co., Richmond, Cal.
2—Mine & Smelter Supply Co., Denver, Colo.
3—Hendrie & Bolthoff Manufacturing & Supply Co., Denver, Colo.

The costs of flotation oils have varied so much, owing to the unsettled market, that it is almost impossible to give an idea of what they should cost. For a rough estimate it is possible to say that crude petroleum will cost the same as for other purposes. Many of the specialized products such as coal tar, listed above, will cost about 5c. or less per gallon. The coal-creosotes and the wood creosotes cost 15 to 30c. per gal.; the pine oils 15 to 60c., and eucalyptus oil will cost $1.50 or more per gal. The effect of the ending of the War as regards coal-tar and creosote in the American market is uncertain, but, so far as known, wood products will not be affected, and petroleum products for flotation will almost certainly be little affected. Flotation men do not like to have their oil costs go over 5c. per ton of slime treated, and many costs are nearer to 2c., or possibly even less.

There can be no doubt that the higher-grade pine-oils and other wood-oils are the best adapted to general flotation work, but the question of what is commercially feasible is entirely different. Thus, the wood-creosotes are meeting with much favor. Many of the special petroleum products, especially those high in sulphur, are adaptable for rough concentration of copper ores, but the most favored materials for such ores at present seem to be the coal-tar products in combination with topped crude petroleum, oils from which the lighter fractions have been removed by distillation. Coal-tars and creosotes, with a small addition of pine-oils, are being used a great deal in zinc work, and the wood-creosotes find favor in the treatment of galena ores. Gold and silver ores seem to require much pine-oil, although the pine-oil can be diluted with some of the coal-creosote oils.

It will be found that there is a considerable number of oils that will give good results on any given ore, if the mechanical treatment is adjusted to suit each given oil.

Following is a table showing the amount of flotation-oils being consumed every month throughout the United States. These figures were collected at the beginning of 1916 by direct communication with the companies.

MONTHLY CONSUMPTION OF FLOTATION-OILS IN THE UNITED STATES

Type of ore	Monthly tonnage of ore: Beginning 1916, Tons	Monthly tonnage of ore: End of 1916, estimated, Tons	Monthly consumption of flotation-oils, beginning of 1916, lb.: Wood products: Pine-oil	Pine-tar oil	Eucalyptus	Creosote	Turpentine
Copper	1,248,000	1,942,000	59,300	750	...	417,000	1,500
Zinc and complex	248,000	350,000	60,750	667	...	262,500	3,330
Lead	115,000	136,000	3,900	...	216	121,000	....
Gold and silver	45,700	123,000	9,830	750	...	40,250	....
	1,656,700	2,551,000	133,780	2,167	216	840,750	4,830

Type of ore	Monthly consumption of flotation-oils, beginning of 1916, lb.: Oleic acid	Coal products: Tar	Creosote	Cresol	Petroleum: Crude	Fractions
Copper	....	677,000	403,000	8,340	79,000	1,702,000

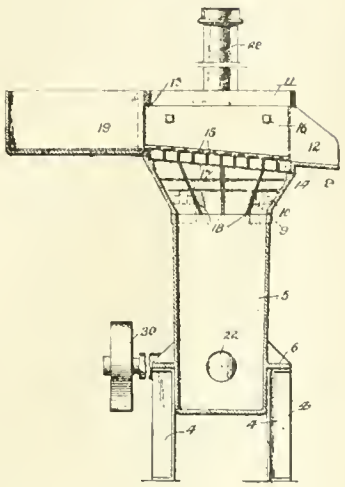
Recent Patents

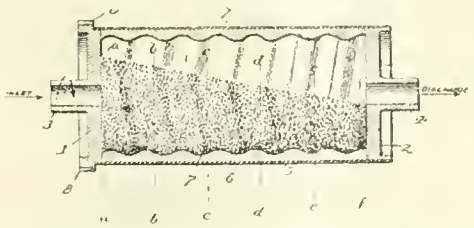
1,176,403.—Pulsator Riffle-Jig. Robert H. Richards, Boston, Mass. Filed Aug. 13, 1914.



1. The combination with a jig including a screen and means for producing a unidirectional pulsing upward flow of water therethrough, of a plurality of transversely extending riffles, having an inverted L-shape in cross section mounted directly above the screen.

2. The combination of a sluice having an opening in its bottom; a screen mounted in said opening; a hutch beneath said screen; a plurality of closely spaced inverted L-shaped riffles extending transversely of said sluice mounted immediately above said screen with the upper flanges extending substantially horizontally in the direction of gravital flow in the sluice; and means connected with said hutch for producing a pulsing flow of water through said screen and riffles.

1,172,673. Grinding-Mill. David Cole, Tucson, Ariz. Filed Nov. 10, 1913. Serial No. 800,184. (Cl. 83—9.)



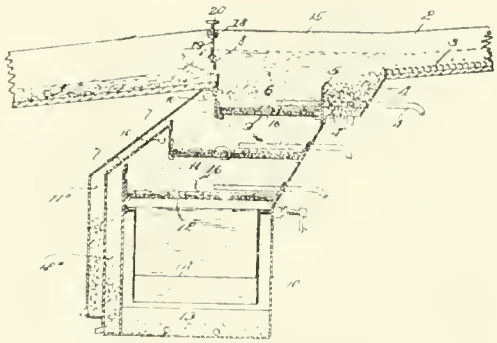
1. In a grinding mill, the combination of a rotatable hollow drum adapted to receive material at one end and discharge it, when ground, at the other end, and having a reversely feeding spirally corrugated inner surface; and means for rotating said drum, the spiral being of a direction to move the larger bodies of the charge in contact therewith, toward the inlet or receiving end of the drum when the latter is rotated in its normal grinding direction.

1,170,665. Concentration of Ore. Edward Hoit Nutter, San Francisco, Cal., assignor to Minerals Separation American Syndicate (1913) Limited, London, England. Filed Aug. 31, 1915. Serial No. 48,169. (Cl. 83—85.)

1. A process of concentrating ores which consists in mixing the finely crushed ore with water, adding a minute quantity of a product obtained by treating a hydrocarbon (composed exclusively of hydrogen and carbon) with sulfuric acid, agitating and aerating the mixture to form a froth, and separating the froth.

2. A process of concentrating ores which consists in mixing the finely crushed ore with water, adding a minute quantity of a product obtained by treating a mixture of hydrocarbons (composed exclusively of hydrogen and carbon) with sulfuric acid, agitating and aerating the mixture to form a froth, and separating the froth.

1,173,465. Dredge Sluice-Jig. Donald Steel, Palo Alto, Cal. Filed Dec. 24, 1914. Serial No. 878,865. (Cl. 83—58.)



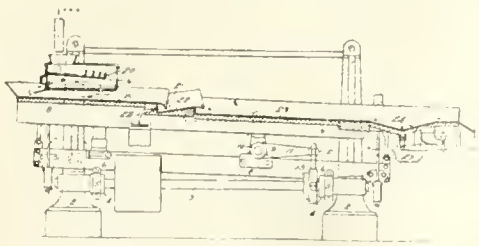
1. In combination, a sluice, a concentrating apparatus interposed therein for segregating the solids and values from the feed material, a trap to check the flow of material thereto and having means for supplying a rising stream of water for gently feeding part of the solids to said apparatus, an adjustable gate on the discharge side of said apparatus above the over-flow level of the trap for regulating the flow and depth of quiet water above said apparatus, and a dam below said gate to regulate the depth of solids held in the apparatus.

1,170,637. Ore Concentration. Arthur Howard Higgins, London, England, assignor to Minerals Separation American Syndicate (1913) Limited, London, England. Filed Aug. 31, 1915. Serial No. 48,177. (Cl. 83—85.)

1. A process of concentrating ores which consists in mixing the finely crushed ore with water, adding a minute quantity of a sulfuric acid derivative of an organic body, agitating and aerating the mixture to form a froth, and separating the froth.

2. A process of concentrating ores which consists in mixing the finely crushed ore with water, adding a minute quantity of a sulfuric acid derivative of an organic body and a small quantity of acid, agitating and aerating the mixture to form a froth, and separating the froth.

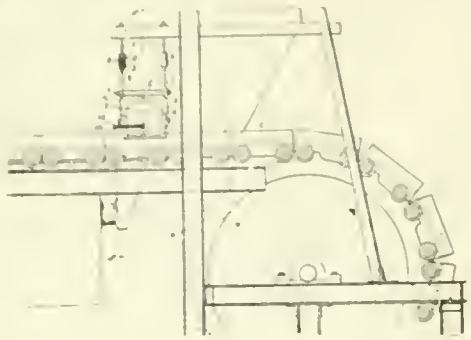
1,172,171. Pan-Motion Amalgamator. Karl Senn, Alameda, Cal. Filed Dec. 26, 1913. Serial No. 808,703. (Cl. 83—68.)



1. In an amalgamating apparatus, a table arranged at an incline and having an amalgam plate at its high end, said table having a pocket adjacent said high end, the inner end

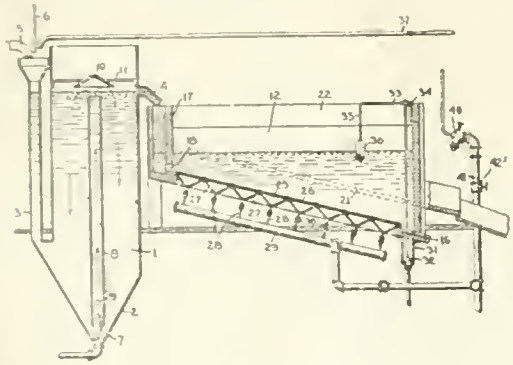
of the plate being downturned to extend in the pocket, an amalgam plate in the pocket having its outer end inclined downwardly in a direction toward the high end of the table and having its tailing end turned downwardly, a third amalgam plate on the table having one end underlying said tailing end of the second amalgam plate and having its outer end portion concaved to form a pan the bottom of which extend below the plane of the third plate, said pan having a discharg outlet and said pocket also having a discharge outlet.

1,179,390. Sintering Machine. John F. Austin, Monterey, Mexico, assignor to The American Smelting & Refining Company, New York, N. Y., a Corporation of New Jersey. Filed June 18, 1913. Renewed Sept. 17, 1915.



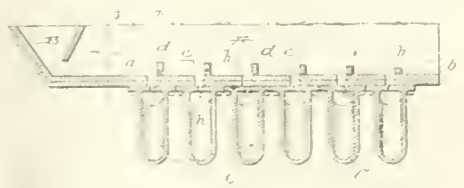
1. In a sintering machine, the combination with a movable carrier for the material to be treated, of an ignition device arranged above said carrier, said ignition device comprising a combustion chamber having an opening therein to receive the upper portion of the material on said carrier, and means for supplying a combustible fuel to said chamber.

1,180,089. Process and Apparatus for Separation of Ores by Flotation. Albert W. Thompson, Fitchburg, Mass., and David Cole, El Paso, Tex.; said Thompson assignor to G. M. Parks Company, Fitchburg, Mass., a Corporation of Massachusetts. Filed Jan. 13, 1916.



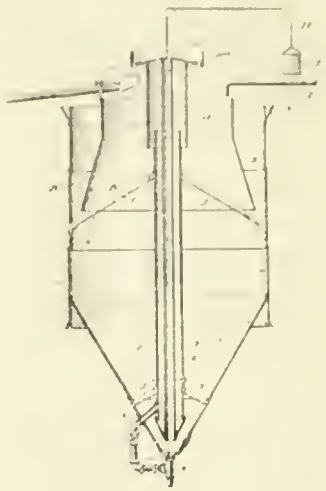
1. An improvement in the step of breaking down the froth in the flotation process of recovering metallic contents from ores, which consists in impinging the froth with a jet of gaseous fluid commingled with globules of a liquid.

1,170,848. Apparatus for and Process of Classifying Minerals. Robert H. Richards, Boston, Mass. Filed July 25, 1907. Serial No. 385,503. (Cl. 83—82.)



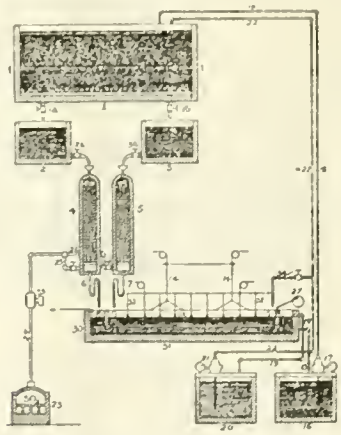
1. A classifier having a pocket of substantially constant area in horizontal cross-section throughout its entire depth, and having a chamber below said pocket in communication therewith by a thoroughfare both concentrated and constricted with reference to at least one dimension of said pocket measured in a horizontal plane, whereby quicksand conditions may be maintained in said pocket and a high velocity of flow in said thoroughfare, a water inlet to said chamber, and a discharge from said chamber for heavier grains or particles previously passed through said thoroughfare.

1,179,658. Agitating and Settling Tank. John E. Rothwell, Butte, Mont., assignor to Colorado Iron Works Company, Denver, Colo., a Corporation of Maine. Filed Apr. 11, 1914. Serial No. 831,298. Renewed Sept. 10, 1915.



1. An apparatus of the class described comprising a tank, means for maintaining agitation therein, means for simultaneously withdrawing clear liquid therefrom and means above the normal level of the contents of the tank for withdrawing a portion of the material circulated through the agitation means.

1,179,522. Process of Extracting Metals From Their Ores. William E. Greenawalt, Denver, Colo. Filed Sept. 30, 1912.



1. A process of extracting metals from their ores which consists in treating the ore with dilute sulfuric acid; separating the resulting rich metal sulfate solution from the gangue and introducing it into the cathode compartment of an electrolyzer; washing the residue and introducing the washwater into the anode compartment; then electrolyzing the solutions, whereby copper is precipitated at the cathode and the acid radical transferred to the anode, thus enriching the anolyte in acid; rejecting the cathode solution; returning the anode solution to the ore which in turn becomes the metal solution to be electrolyzed as the catholyte while fresh washwater is used as the anolyte, and repeating this cycle of solution, precipitation and regeneration as often as necessary to get the desired results.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MAGALIA, CALIFORNIA

Past and Present.—Lode and Drift Mines.

The Magalia district of Butte county is experiencing a real live revival. It has been a famous gold producer in past years, approximately $50,000,000 having been taken from drift, placer, and surface mines within a radius of 10 miles of Magalia. The third largest nugget in the State was found here in the Willard claim or Red Hill, it weighing 832 oz., worth $13,312. This claim also produced a 132-oz. nugget, and several weighing from 70 to 145 oz. The Persehbaker or Magalia drift mine was exceedingly rich in its day. For a generation the district has slumbered, with only a small amount of work being irregularly done; but the past few months have witnessed a change, with some really important developments.

The Springer and Mathewson mines on the Mathewson dike, 7 miles from Magalia, have been bonded by Harry M. Thompson representing San Francisco capital. A steam-shovel of 1500-cu. yd. capacity in 10 hours has been operated for two mouths. Working with this machine is a large crusher followed by rolls reducing ore to 1-in. size. From the rolls the product is run through sluice-boxes to catch the coarse gold. The head and tail samples are carefully assayed. If the latter are worth it they will be re-ground in tube or ball-mills. At present the work is entirely for sampling purposes. The vein-matter being opened is extensive. Ten men are employed. Results have been so satisfactory that last week the sampling was stopped. A concentrating plant is now being erected.

The Willard claim, or Red Hill, as it is better known, four miles from Magalia, has been bought through W. E. Young for San Francisco people and will be operated at once. The purchase price is reported to be $10,000 cash. This property has been idle for nearly 20 years.

The Eureka (quartz), on Little Butte creek, has been examined recently by an engineer and a deal is expected in the near future. The property is owned by C. Crowder and others of Chico, who recently purchased it from J. Mugford and associates, all local people. At present a drift-channel is being opened. Eugene Richards is foreman and 8 men are employed.

W. F. Anderson has bonded a quartz property at Yankee Hill; operations will be started this summer.

Rich ore has been found at the Smith-Understock quartz mine on the west branch of Butte creek. A cross-cut to the vein was driven 120 ft. The ore shows plenty of free gold. The title to this property is in dispute at present, hut the owners have a good property.

The drift mines are active also, as is shown by the following:

The Robinson, on the west branch of Butte creek, is being opened by J. A. Veatch, backed by San Jose and Napa people. Eight to ten men are employed, and an incline is being driven to open the old river channel. This company is also operating the Royal drift mine, four miles below the Robinson. Six men are at work extending the main adit to cut the channel. The report that this company has under option all of the drift mines along the Big Butte ridge is erroneous, as the titles to some of these claims are in dispute, the railroad lands also being mixed up in it. Carelessness in the matter of assessment work is the main cause of trouble in most cases.

The Oro Fino is producing, with W. F. Anderson in charge of 6 to 8 men.——At the Blue Hog, near Magalia, 6 men are working under J. Evans. This drift mine is owned by Los Angeles people, and is at present under bond to San Franciscans.——The old Thompson drift mine above Magalia is being opened by G. C. Allen and Chico men. An incline is being sunk to the channel. Four men are employed.——J. F. Littlefield, representing the Sutro interests, is at work with 4 men on a drift-channel adjoining the Eureka property on Little Butte creek.——The well-known Mineral Slide drift mine on Little Butte creek, from which over $1,000,000 has been extracted, is expected to resume operations shortly.—— The Lucky John drift mine adjoining the Mineral Slide is being opened by J. D. Hubbard and associates, with 4 men.

Judging from the number of engineers and others looking for gold mines, that have been in Magalia during the past month, it seems as if the old district is about to take on a new lease of life. The gold is more difficult to win now, but plenty of it is left. Once capital becomes interested in drift-mining, and good results are secured, more will be obtainable.

MEXICO CITY, MEXICO

Some Pertinent Remarks on Mexican Conditions

In my letter published in the Press of January 29, I stated that the dominant faction, the Carrauza, was the "best-behaved" of all; but in order that no false hopes may be raised in the breasts of mining men by this adjective, I shall now endeavor to explain what is meant by good behavior from a Mexican revolutionary faction. It is curious that the Liberal leader, Venustiano Carranza, should have been—like his arch reactionary enemy, Victoriano Huerta—a graduate of the Diaz school of *cientificos* or systematic grafters. However, such is the fact, and all available evidence indicates that the State army which Carranza used, when he first led his Constitutional army against the usurper Huerta in 1913, had originally been got ready to fight Madero, because the latter had been so officious as to undertake to investigate the disappearance of Federal funds entrusted to Carranza as governor of Coahuila. If Huerta had been a different man, he might have succeeded in his usurpation in spite of both Carranza and President Wilson; but as his only mental equipment was a certain bulldog tenacity and ferocity, he was bound to fail in his attempted task of restoring the *hacendados* or slave-holders to power. Huerta was not shrewd enough to understand that the Madero revolution had tolled the knell for Mexican peonage, and that no ruler can re-enslave his native masses when once they have been awakened, unless he possesses an irresistible force of alien mercenaries. Moreover, whatever military sagacity he possessed was continually befogged by douches of brandy, which liquid was likewise the inspiration for his numerous political assassinations, performed in a style worthy of the best traditions of the African Gold Coast.

In spite of Huerta's political blunders and military stupidity, Carranza made little headway against him until he was lucky enough to get the aid of that invincible pair: Villa and Angeles, the first, a born leader of ruffians; the other a foreign-educated officer of artillery. The removal of the United States embargo on arms, in February, 1914, was soon followed by the fall of Huerta's stronghold of Torreon. And the seizure of Vera Cruz, two months later, by Admiral Fletcher, and the loss

of Zacatecas soon after, led Huerta to start for a European trip while the going was still good.

The entrance of the Constitutionalists into Mexico City, in August 1914, was hailed with joy by resident Liberals, even though the judicious were grieved at the vast amount of stolen property, especially horses, that was flaunted by the victorious liberators. This grief was increased when the residents were initiated into the mysteries of 'intervention,' which implied the wholesale seizure without payment of private houses, automobiles, or anything else that happened to be defined as a "military necessity" by the various generals. The climax came when Luis Cabrera, the spokesman of Carranza, arose in the general military convention of September and announced an indefinite suspension of the Constitution, and its guarantees of individual rights, in order that the Revolutionists might avoid any legal obstacle in their work of reconstruction. Curiously enough the Convention, when it had moved from Mexico City to Aguascalientes in October and deposed Carranza as First Chief in favor of Eulalio Gutierrez, announced its adherence to the Constitution. So, thereafter, there existed the anomaly—possible only among a people as illogical as the Mexicans—of a 'Constitutional' party repudiating the Constitution and of an 'Anti-Constitutional' party accepting it.

In the subsequent fratricidal struggle between Carranza and the Convention (described in my letter of April 8) the "unmorality" of the Mexican people was never better exhibited than by the apathy with which they viewed the unscrupulous methods, used by both sides for partisan advantage, from the disregard of life and property to the incitement of race hatred. Thus, several Vera Cruz policemen were shot by General Candido Aguilar for the heinous offense of continuing at their posts during the American occupation. During February 1915, when General Obregon was "castigating" Mexico City with the help of Dr. Atl, he had that adventurous artist select a number of the best paintings in the National Museum, and soon thereafter these treasures mysteriously disappeared from their frames and started for parts unknown. But the most abominable of all the crimes of the Mexican liberators has been their organized system for starving the very people they came to liberate. This system was first used extensively by General Obregon in Mexico City during the punishment inflicted for its partiality to the Convention. It involved the stoppage of wholesale food importation, by failure to provide railroad-cars, and the closing-down of the chief employing concerns, by various devices. Among the latter, the most effective was the organization or encouragement of the local unions of the *Casa del Obrero* (I. W. W.) by the clever Dr. Atl. For, with an enthusiastic 'local,' a Government agent, in the guise of a 'comrade,' could easily call a strike and force a factory to shut-down rather than yield to his impossible demands. When food became dearer every day, and no work was obtainable, the workmen had the choice between Carranza's army and starvation, but the helpless women and children had only the latter alternative.

In the case of the Mexico City tramways, the Government got up a strike as an excuse for 'intervention,' in 1911, and has since operated them, as it is also now operating all the privately-owned railroads. In Mexico City the American Red Cross and a German relief society fed thousands for a while, but in October, Carranza prohibited further foreign charity, and the stricken masses began again to perish rapidly of famine and typhus. At first, the famine was artificial, having been organized by Obregon to recruit the army; but it soon became genuine, owing to the wholesale export of food during the spring of 1914. Part of this export was conducted directly by Carranza, in exchange for foreign munitions, and the balance was handled by all sorts of traders, who rushed to enjoy the huge profits incidental to exportation from a country in the throes of a rapidly depreciating currency.

Although the export taxes had been put on a gold basis and greatly augmented, the Mexican currency fell much faster than prices rose. As Carranza saw that the lion's share of the profit from exportation was still flowing into private pockets, he decided to organize an export monopoly. This monopoly was called the *Casa Exportadora, Angel La Garda* and its artful combination, for its own ends, of the different branches of the political administration, indicate that the ingenuity of the Mexican mind has been greatly underrated by some critics. The export monopoly utilized the services of the Federal, State, and Municipal governments and of the railroads (all of which are now 'intervened' by Carranza) in the following manner: The Federation prohibited the export of food from the national territory, while the States prohibited its export beyond their own boundaries, and installed 'prebostal' committees to fix its selling price. Each municipality had also a prebostal subcommittee. Finally, the Casa La Garda was given first choice in the assignment of empty railroad-cars.

The trap being set, we may now watch its functioning in a certain maize-raising State during the autumn of 1915. Owing to the export of the old crop, the new maize began to sell at the hitherto unknown price of $60 (Mexican paper) per hectolitre (2.75 bushels). Immediately the Prebostal Committee came to the rescue of the "defrauded masses' and to save them from the "unscrupulous greed of the traffickers in human misery" announced a legal maximum price for maize (beyond which no one could sell under pain of confiscation) of $30 per hectolitre. The producers were astounded, but helpless, and most of them hid their maize to await a better price. Soon the big producers were visited by the suave agents of the Casa La Garda and offered $40 per hectolitre for their grain. Fearing discovery of their stock by the Prebostal Committee, and a possible confiscation on the charge of "hoarding," many producers accepted the La Garda offer and delivered their hidden maize to its waiting railroad-cars. Then, in spite of State boundaries and port detectives, the La Garda grain found no obstacle in soon reaching the hold of an Atlantic liner, and departing on its mission to finally gladden the heart of some European chief of commissary. As an additional perquisite, the Casa La Garda controlled its returning empties, and lucky was the importer who could secure one of them for a premium (beyond the railroad charges) of less than $3000 per car.

The result of these adroit maneuvers of the Casa La Garda was that the price of the staple foods—maize and beans, which had weakened a little at the time of the autumn harvests of 1915—began to soar again in December and in February 1916 reached the prices of the August famine. At present writing, food prices on paper are far beyond the February level and are following closely the equivalent prices abroad in gold. Had the export-prohibitive decrees of last October been really enforced, the price of food would have continued on the basis of local paper money and thousands of the innocent victims of starvation and pestilence would now be alive. In only a few industries has it been practicable to advance wages as fast as the rise of prices.

Ostensibly, the vast profits of the Casa La Garda go to the Government, to pay the huge expenses involved in the maintenance of its army of 150,000 men. And though many affirm that the bulk of the profit is really diverted to the gaping pockets of the inner ring of Carranza generals and politicians, I have no conclusive evidence on this point. But whoever gets the gain, the results of the export operations are equally disastrous for the proletariat, whom Carranza came to "rescue and save." The very perfection of the La Garda export machine will tempt its controllers to continue its functioning long after any military excuse for it has ceased; and in this event the Mexican people are surely doomed to decimation by a famine of a severity and extent unknown even in Hindustan.

The paper-money plague (described in my January letter) still overshadows and hoodoos all commercial transactions. The Government acknowledges the issue of ₱700,000,000 of genuine Provisional Government and Constitutional Army notes, while the number of 'counterfeit' bills is legion. Gen-

eral Gringas was shot dead last summer by his own Carranza faction for the crime of passing counterfeit money, strangely enough within a year of surviving a volley from a firing squad of the opposite party. The Gringas operations involved mostly the circulation of ₱50 and ₱100 Provisional-Government bills, and were the cause of the extensive official 're-sealing,' which was practised subsequently to ensure the genuineness of these denominations. There is good reason to believe that General Gringas was simply a scapegoat for men higher up, and that these latter were among the chief officials of the Carranza treasury department.

On May 1, when the old notes had already reached a value of below 2c. (U. S.) per *peso*, they began to be replaced by a new issue of "unfalsifiable" bills which are redeemed in gold, at the rate of 10c. (U. S.) per *peso*, by a newly appointed *Comision de Cambios*. The old notes are decreed to be worth only one-fourth as much as the new notes and are continued as legal tender only until July 1, beyond which date probably no one, not even the *Comision de Cambios* itself, knows what will be their status or value.

The handling of the Carranza paper money has exhibited as much knavery but much less cunning than that of the export monopoly. In fact, the main reliance for the success of the former has been the paper decree. These decrees have formed the chief literary output of the Revolution and have been printed by the million and posted everywhere—a fresh one nearly every day—to announce to the victims the intentions of their "benevolent" rulers. Nowhere—not even in an American legislature—has there ever existed such a childlike belief in the efficacy of human fiat. Every subject has been tackled, from the fixation of prices and wages to the compulsory literatization of the whole peon class within eight months, but, luckily for the victims, the enforcement of the new decrees has usually lagged far behind their announced content.

Perhaps the worst mistake in the fiat-money operations has been the gradual repudiation by the Government of its own notes for the payment of public dues. After putting the mining, the export, and the import taxes on a gold basis, it announced, on May 1, a gold basis for railroad-fares and freight-rates. Though the subsidized I. W. W. propaganda (described in my January letter) was suppressed last February, the I. W. W. unions still remain, and these recently declared a general strike of railroad men who demanded the payment of wages on a gold basis. After being out two days the strikers were put under martial law and ordered back to work, pending "due consideration of their grievances." This strike indicates that the worm has at last turned and that the workers are beginning to refuse to be the chief victims of the rule of fools and of rogues, posing as reformers. If the demands of the railroaders are granted, the Army will be the next to request the payment of its wages in gold, and this event is liable to finish the Carranza régime. As the Mexican army has no commissary, a soldier must buy his food from his pay. Under Diaz, the daily wage of the common soldier was 62 centavos; this was increased to ₱1 under Madero and ₱1.50 under Huerta. But these wages were all in silver, while the ₱2.50 rate, now paid by Carranza, represents only 25 centavos in silver, and with food prices approaching a gold basis the soldier is finding it increasingly difficult to live on his wages.

At present, the two chief obstacles to the general resumption of operations by equipped mines are the lack of railroad transport and of protection for life and property. Thousands of locomotives and cars have been destroyed since 1911, and the survivors are mostly monopolized for the Army, the Casa La Garda, or by some local general as his personal perquisite. Even the ownership by a mining company of its own rolling-stock gives no assured relief, for such is liable to be "intervened" at any time for military purposes. Only a few rich districts, like Pachuca, have enjoyed anything like regular transportation, and this is due to sheltered locations and the fiscal interest of the Government in maintaining the bullion outputs of the operating companies. Even these properties are not able to work at full capacity.

The danger of brigandage takes two forms: first, it may come from the visits of organized bands of rebels, who may merely collect all the arms, powder, and cash in sight and depart, or stay and make a systematic clean-up of everything from the brass pump-valves to the manager's underwear; and second, it may arise from the discharge of a vicious workman, who is liable to seek revenge by joining the local garrison and return a few days later to attack his erstwhile employer, accompanied by a group of fellow-soldiers as unscrupulous and blood-thirsty as himself.

Like his reactionary predecessors, Carranza maintains a rigid censorship and a complete collection of official newspapers to supply misinformation to a credulous populace. In the Capital are the morning vultures *El Pueblo* and *El Democrata*, and the evening viper of the literary Dr. Atl called the *Accion Mundial*. There is also the weekly *Revista Nacional*, and a separate daily for nearly every State capital. In Mexico City is established an official press bureau, guided by two American newspaper men whose function is to censor all foreign telegrams and to prepare such local bulletins as are considered suitable for foreign consumption. The limitations enforced by law and public opinion, on even the yellow journalist of the United States, do not bother his Mexican brother, provided the latter has loyalty to his temporary political chief and literary skill; his pen is as free as the wind, and neither truth, decency, or consideration of consequence need hamper the soaring or sinking of its composing muse.

In spite of the above facts, the existing woes of Mexico are not entirely due to Carranza's incompetence or his subalterns' viciousness; they proceed as much from historical and social causes. Indeed, many of the Federal and State executive departments now contain various well-intentioned officials; and if few of these have the knowledge and ability required for efficient work, this is a result of the wretched educational system maintained by the Diaz dictatorship. For this reason, no executive efficiency can be expected from any Mexican régime of this generation that chooses to continue the present rule against the employment of foreign experts in public offices.

The Diaz usurpation of 1876 arrested the progress that Mexico had been making toward self-government under Juarez and Lerdo de Tejada. Though Diaz and his rascally henchmen were shrewd enough to maintain peace (so as to encourage the foreign enterprises, from whose legal and illegal taxation they thrived), they left the official and educated classes of Mexico in a much worse moral and mental state than they found them. The destructive anarchy, now so prevalent among even the Carranza leaders, simply arises from the possession of modern weapons by men who have never been disciplined by education, and have followed their own wild impulses from the cradle upward. If Mexico could find a local Kossuth or Garibaldi she might hope for salvation from even her present dreadful plight; but as such a discovery is most improbable, it is considered by thoughtful natives that the only remedy is an appeal to the United States for such aid as she gave Cuba under like circumstances.

At all large sales here of New York exchange, Army officers are eager buyers and hundreds of them now have tidy fortunes, safely deposited in American banks, as the concrete result of three arduous years of patriotic labor. It is unlikely therefore that many of Carranza's officers will care to fight the country where their fortunes are deposited and where they soon expect to move to enjoy them. As for the rabble of peons, ranging in age from 7 to 70 and impressed into the Army by starvation, they have little love for their leaders and less for their Government. Thus, the American punitive expedition, should it decide to stay indefinitely in Mexico, might be heartily welcomed by everyone except Carranza; and his resistance would probably be restricted to big words at long range.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Thirty-three miles of track is completed on the railroad from Anchorage, allowing fairly fast trains to run. On the branch line to the Matanuska coalfield there are 670 men at work. At all points there are 2024 men on the pay-roll, also 200 horses. On May 19 Congress at Washington voted an appropriation of $6,247,000 for the railway.

Chisana

It is reported that A. McGettigan and others have discovered rich gravel 20 miles from Shushanna City.

Juneau

The Alaska Gold Mining & Development Co. has been incorporated by Carl E. Lund and Ray H. Stevens of Juneau and John McWilliams of Douglas, with a capital of $1,000,000 to acquire, develop, and operate mining properties wherever found.

The incline shaft at the Ready Bullion mine was completed to 2488 ft. depth, with an inclination of 70°, on May 24. Sinking and raising connected with great exactness, credit being given to the surveyor at the Alaska Treadwell, J. Johnson. Work commenced on March 19, 1915. The completion of this shaft, although an expensive undertaking, will be a money-saver. Ore will now be hoisted to the surface at a saving in some instances of over a quarter of a mile haul. The old shaft will be used for filling only.

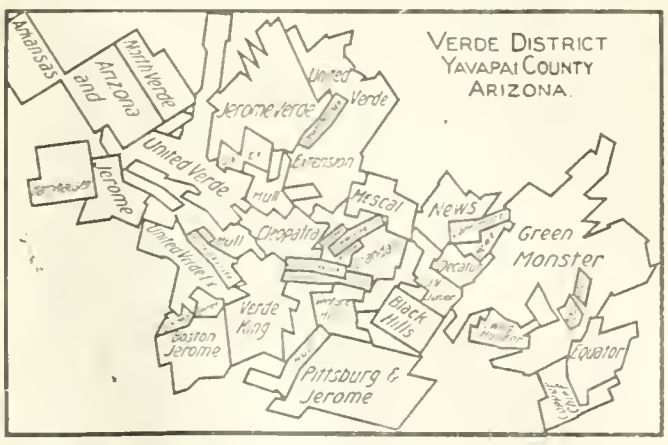
Valdez

According to the Valdez *Miner*, the season for the Prince William Sound copper mines opens full of promise and with increased activity. The Latouche, Ellamar, Granby, Three-Man, Alaska Mines, Reynolds-Alaska, Seattle-Alaska, Thomas, Dickey, and many others on the mainland and islands in the Sound are developing well.

ARIZONA

Yavapai County

Churn-drilling is to be done at the Shea property, adjoining the Copper Chief at Jerome. This is the first time that any



ground at Jerome has been so prospected. A. P. Thompson is in charge. The Copper Chief is shipping 30 tons of ore daily, also treating some ore locally.

Following the action of the Green Monster company, the Boston & Jerome Copper Co., whose property is south of the United Verde, has listed its stock in San Francisco. The United Verde Extension is producing 200 tons of 15% copper ore daily.

Cochise County

For the sum of $600,000 the property of the Leadville Mining Co. of Courtland has been optioned to the Needles Mining & Smelting Company.

Property of J. Letson and D. F. McGarry near Bisbee has been acquired by the Arizona-Bisbee Copper Co., recently formed at Phoenix. Extensive exploration will follow at an early date.

CALIFORNIA

The second annual California first-aid and mine-rescue field meet will be held at Sacramento, during the State Fair, on September 6. This meet will be held under the auspices of the California Metal Producers' Association, assisted by the Industrial Accident Commission, and the U. S. Bureau of Mines. Entries should be sent at the earliest possible date to Robt. I. Kerr, 1109 Merchants National Bank building, San Francisco, by August 1.

Amador County

(Special Correspondence.)—The new stamp-mill for the Argonaut mine at Jackson is being constructed by the Knight company of Sutter Creek. The new mill is to replace the present one, and will be erected on the opposite side of the hill to the west of the present plant, the change of site being favored because of the better facilities for impounding tailing. From the new mill-site, the residue will flow by gravity to the large natural basin, at the lower end of which a concrete dam 400 ft. long and 40 ft. high at the lowest point is nearing completion. This structure is being built under contract by Bent Bros. of Los Angeles at a cost of $25,000, and will be known as the Eastwood dam, after the company's consulting engineer, F. Eastwood. An underground hoist has been installed at the lowest level of the Argonaut mine, which will make possible the sinking of the shaft an additional 3000 feet.

Persistent rumors are afloat to the effect that the Moore mine, south of Jackson, is shortly to be re-opened by W. J. Loring and A. Burch, well known in these parts. The title was cleared, and papers in the transaction prepared prior to Mr. Loring's recent trip East.

The Central Eureka company has accepted the resignation of J. E. Davis, who has superintended the property for several years, and appointed in his stead a Mr. Jose of San Francisco, who recently had charge of operations at a mining property at Towle, Placer county. C. E. Julihn was employed by the company to make an examination of the Central Eureka property to ascertain whether the shareholders would be justified in paying another assessment to carry on the work. His report shows that only a middle section of the lode has been explored, and that other veins will undoubtedly be developed on both sides of this middle portion. Just as productive veins have been proved in adjacent mines in the vicinity of the hanging and the foot-wall of the lode. He also recommends sinking a winze from the 3200-ft., the present lowest level, to 3300 ft., claiming that there are substantial prospects for more ore in depth, judging by the ore-shoots

worked above 3200 ft. A 5c. assessment has been levied. The mine is equipped with an electrically-driven 40-stamp mill, steam hoist, electric pumps, and other modern machinery. The shaft is in excellent condition.

Sutter Creek, May 31.

Calaveras County

(Special Correspondence.)—An option and lease have been taken on the Ozark gravel mine, Six-mile creek, near Angels Camp, by R. E. Herndon, C. Fishman, and D. Headington. The property has been unwatered and the old workings cleaned out and re-timbered. A 10-hp. hoist and a rotary mill have been installed, all driven by electric power. Mr. Herndon is resident there. New ground is being opened, and it is expected that the mill will soon be treating good gravel from the lower channel.

The Economic mine near Esmeralda is being operated by the Standard Amalgamated Exploration Corporation. Equipment consists of a 20-stamp mill and a gasoline-driven electric lighting plant. A 100-hp. motor-driven compressor is being installed, electric power supplied by the P. G. & E. Co. The property has been extensively developed from the adit-level. The main adit is out 1100 ft. north, from which an east cross-cut has been run 1200 ft., and a west cross-cut 400 ft.; 1400 ft. of raises have been put up, and a large body of ore has been developed. It is expected that the stamp-mill will be started in about 30 days. L. Robin is superintendent and consulting engineer.

Angels Camp, May 22.

Eldorado County

At the Montezuma mine, 10 miles south-west of Placerville, the new shaft is down 830 ft. Cross-cutting is under way at 500 and 800 ft., where on both levels wide shoots of $5 to $10 ore has been opened. The mine is under option to G. Wingfield and W. J. Loring of the California Exploration Co.——Development in the Rhetta, south of the Montezuma, is reported to be very satisfactory.

Nevada County

In the east drift at 1800 ft. in the Providence mine of the North Star company rich ore has been opened, much of it containing telluride of gold.

Six feet of ore showing free gold and arsenical pyrite has been cut in an adit of the Red Ledge mine, near Washington. Williamson brothers and C. Cole are owners.

Plumas County

(Special Correspondence.)—The Engels Copper company has commenced cross-sectioning its survey (location) for a railway up Indian creek from the Western Pacific line to the mine. The present transport scheme for concentrate is aerial tram to Lower Camp, then in three wagons, carrying 25 tons, hauled by a caterpillar-tractor, using distillate, to Taylorsville, finally to the W. P. line at Keddie by motor-truck. The light steel bridges on the county roads make the last change necessary.

A number of prospects in this district are worthy of attention.

Taylorsville, May 26.

COLORADO

During June the leading metal producers in the State will raise wages, affecting 5000 miners. It is thought that the increase will be general, benefiting a total of 25,000 employees.

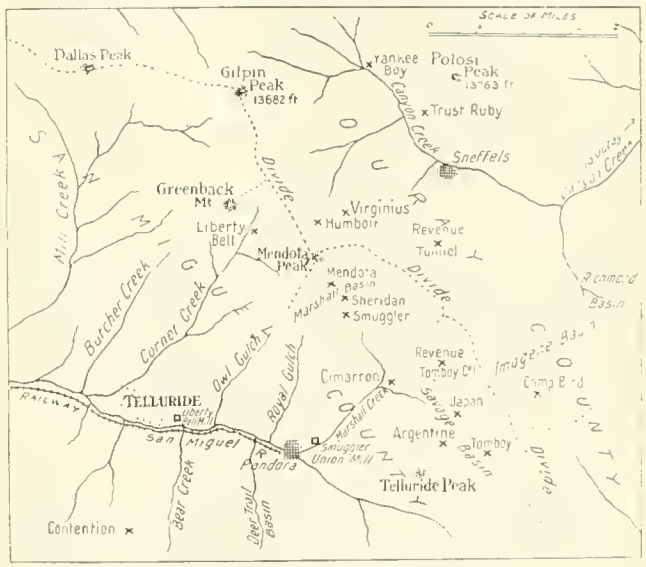
Boulder County

(Special Correspondence.)—The Blue Jay and Burnt Mountain claims in the Nederland tungsten district have been taken over by J. Conners of Oatman, Arizona, and S. T. Weller of Denver. A company called the Tungsten Girl Co. will operate the properties. In the transaction a good deal of cash changed hands, while the original owners will receive royalties until the total price is paid. Both mines have good prospects. Ore will be treated at the National Tungsten Co.'s mill, whose property adjoins.

Ward, June 2.

Ouray County

In *The Plaindealer* of Ouray on May 23 a brief history of mining in this county is given by William Rathmell. In September 1874, prospectors located claims. Permanent settlement started in 1876-'77. Up to 1893 the region was considered a silver-lead producer; after that gold predominated.



PART OF THE SAN JUAN REGION.

Such mines as the Camp Bird, Yankee Girl, Guston, and American Nettie were opened later. The country consists of a deeply-scored volcanic plateau, the volcanics lying on a great series of sedimentaries.

The Camp Bird company reports as follows for the first quarter of 1916:

Ore treated, tons	6,813
Bullion and concentrate sold	$215,075
Profit (after deducting London and Paris charges)	135,000
Profit from Santa Gertrudis, Mexico	206,000

Development totaled 1101 ft. There was spent on the cross-cut adit from the mill, $19,421. It is in 329 ft., of the total of 10,700 ft. to reach the vein. The work is to be performed by the Camp Bird Tunnel, Mining & Transportation Co. The measurable ore reserves are reduced to a negligible quantity of about 1200 tons, and there is little prospect of developing any more of consequence in the Camp Bird vein until after the adit has reached the vein. Work in ninth level discloses a character of vein and rich ore showing along the floor fully sufficient to warrant exploration at greater depth. Further, this stretch of ground represents but about 10% of a mineralized vein, the remainder of which can only be worked with any degree of safety, if indeed at all, through a drainage-tunnel; and while it is possible the ground immediately under No. 9 level might be explored by sinking No. 3 shaft, the other 90% of the vein would still remain but partly developed. For this reason it was decided not to sink a shaft that would only partly develop, but to drive a drainage-tunnel, with the completion of which will leave all of the mineralized stretch, some 4000 ft. in length, accessible for exploration at minimum expense.

Teller County (Cripple Creek)

(Special Correspondence.)—The Consolidated Mines & Reduction Co., with head office at Denver, is developing the Buck-

horn Kitty Wells Dante mine, Tenderfoot tunnel, and Ella W. claims. Most of the ore shipped, 3 carloads per week, comes from the Dante. The general superintendent, James A. Force, formerly of San Francisco, states that the company intends constructing a concentrating plant of 500-ton capacity on its property. The millsite has been selected, and building operations will commence not later than September of this year. The mill will be of similar construction to those in general use in the district, differing only in that flotation concentration will be featured to a greater extent than has been heretofore attempted here. It is the intention of the company to give preference to flotation over gravity-concentration, possibly to the extent of eliminating the tables entirely. Future operations of this plant, if proposed plans are carried out, should be of general interest to the mining fraternity.

Cripple Creek, May 28.

Gold output of the district during May was $1,185,840 from 84,150 tons of ore.

IDAHO

Lemhi County

(Special Correspondence.)—Two 25-hp. oil engines, machine-drills, and other machinery have arrived at the Copper Queen mine, 20 miles from Salmon City.

The tungsten mine on Patterson creek shipped 100 sacks of 65% concentrate in April, worth a total of $40,000.

There are more mining deals in progress in the district than for years. An active season has begun.

Salmon City, May 22.

Shoshone County (Coeur d'Alene)

Owing, it is said, to the physical condition of the Marsh mine at Burke, and the company's financial condition, the mine and mill are closed indefinitely. Some directors voted themselves a lease on Marsh ground, in spite of protests by E. Pohlman of Spokane. In April, he said, the mill feed averaged 7% lead; a profit was made on this. On May 15 the cash resources were $15,000. The mine contains 20,000 tons of ore.

The new 125-ton mill at the Hypotheek mine is ready for work. The ore averages 10% lead and 10 oz. silver per ton. Concentrate of 25 to 40% grade will go to the Northport smelter. At 500, 700, and 900 ft. depth the mine has two years' reserves.

Construction of a spur from the O.-W. R. & N. line at Kellogg to the new smelter of the Bunker Hill & Sullivan company is soon to begin. Excavation for the plant is also to commence. W. K. Mallett of Anaconda will be in charge of erection.

The pay-roll for the Mullan district in May totaled $110,000 for labor alone. Of this the Federal paid $60,000; Hunter, $30,000; and National, $10,000.

MICHIGAN

The Copper Country

(Special Correspondence.)—Utilization of mill tailing for underground filling is again in vogue in the different mines of the Copper Range company, where practicable. The Quincy now proposes to use the same system.

There is reason to believe that the Quincy will have but little future trouble from severe air-blasts. Some years ago when the situation was at its worst manager Lawton put into practice the plan of maintaining a 200-ft. solid rock surrounding each shaft as it was sunk. This required the locking-up of a great deal of valuable ore near the shaft, but it was effective, as there have been no air-blasts in any of the lower levels since that time. Every blast, has, on the other hand, occurred at a point half-way from surface to the bottom, and when damage has been done to the shaft proper it has happened where shaft-pillars were particularly narrow. The reason for the hope that there will not be future trouble comes from the fact that shafts No. 2 and 7 "came home," as the Cornish miners says, some time ago. And a couple of weeks ago No. 6 shaft "came home" too, a little late, but doing some damage in getting in. Thanks to foresight there was not a fatality nor a serious injury resulting from the No. 6 air-blast. Further than that, a rearrangement of the miners above the spot where the damage was done made it possible to maintain production of rock at a figure nearly normal. The shaft was damaged for a distance of several hundred feet, and repair work has been hastened to a remarkable extent.

Houghton, May 23.

MISSOURI

Jasper County (Joplin)

When complete early in June, the D. C. & E. No. 2 concentrating plant north of Webb City will have a capacity of 1500 tons per 24 hours. Part of the ore comes direct from the crusher to the rougher-jigs, eliminating a lot of feed to the rolls. Ore is mined at a depth of 131 to 160 ft.

Ore prices declined again due to lower spelter, the range being between $60 and $95 per ton. The lower average basis price for May means a reduction of 50c. per day in wages for June, namely, $3.75. The output of the Missouri-Kansas-Oklahoma region last week was 5822 tons blende, 268 tons calamine, and 992 tons lead, averaging $75, $52, and $92 per ton, respectively. The total value was $545,811.

MONTANA

Lewis and Clark County

With a capital of 1,500,000 $1 shares, the Thomas Cruse Mining & Development Co. has been incorporated. Richard Cruse is president. The Thomas Cruse estate, including the Franklin mine in the Scratch Gravel district, the Bald Mountain mine and other properties, collectively known as the Cruse mine at Marysville, the Blue Cloud and other mining claims in Lewis and Clark county, the Jackson Creek and other claims and real estate in Jefferson county; numerous mining claims in Meagher county; 1000 acres of patented oil-land in the heart of the oilfields near the Montana-Wyoming boundary line, not far from Red Lodge; and real estate in the city of Helena, are to be developed.

Silverbow County

The Butte Workingmen's Union is demanding an increase of 50c. per day in wages, and a strike has started which may spread to great proportions. At present this does not affect the mines.

NEVADA

Clark County

Ore shipments from Goodsprings in April were between 5000 and 6000 tons. Production increases each month, new mines entering the list. Tungsten is being mined at Clark mountain, 31 miles from Goodsprings.

Elko County

(Special Correspondence.)—There are three well-equipped mills in the Gold Circle district, and prospects are numerous. Comparatively nothing is known of the district beyond its immediate neighborhood. We are in the position of most camps which have had a transient boom; a wild rush at the outset, a few strikes of high-grade pockets which were dug out almost as soon as found, then a slow but sure dying out of interest and the consequent desertion of the place. Where money has been spent intelligently results have justified the expenditure. At present one mine here, the Elko Prince, is adding more to the mineral production of Nevada than all the much-advertised Rochester district, yet Gold Circle gets no publicity. Possibly this is the fault of its miners and owners.

Midas, May 24.

Esmeralda County

The Goldfield Consolidated reports for May as follows: ore treated, 32,400 tons; gold recovered, $214,500; profit, $52,500.

Humboldt County

A boulder of antimony ore weighing 640 lb., containing 70% metal, was recently found at the Syndicate mine east of Kodak, which is 6 miles north of Lovelock.

Nye County

Some time next month the Round Mountain Mining Co. will publish a statement regarding its mine, placer ground, and finances. Dividend possibilities will also be discussed.

Work continues at the Pioneer Consolidated at Pioneer. At a depth of 110 ft. $3 to $7 ore is being broken for a width of 10 ft.; also a fair grade across 15 ft. at 170 ft. At 250 ft. is $6 ore over a great width, while rich ore is being sacked. The mill is saving 60 to 70% by amalgamation; tests show that additions to the plant would give 98.85%. Enough bullion is being saved to pay mining and milling.

Tonopah last week yielded 8778 tons worth $183,264. At 1240 ft. in the Halifax is 20 ft. of good ore.

OREGON

Josephine County

On the Illinois river G. E. Anderson has a gravel mine yielding gold and platinum. A recent clean-up from about 20 days' sluicing recovered 122 oz. of gold. About 10 oz. of platinum is saved each winter. Two giants and an elevator are operated.

SOUTH DAKOTA

Lawrence County

A dividend of 2½c. a share, or $12,500, has been declared by the Wasp No. 2 company. The gold ore maintains its average, and a carload of wolframite is expected to sell for $90,000.

TEXAS

Brewster County

(Special Correspondence.)—The recent bandit raid and Mexican disturbances in the Big Bend country of this county have not caused any cessation of quicksilver mining operations in the Terlingua district, which is west of Boquillas. Most of the American mining men along the border have sent their wives and families to the interior as a matter of precaution. The International Mining Co. expects to resume operations at its mine, situated just across the river in Mexico from Boquillas, at an early date.

The old Buick mine, situated in the Boracho district, not far from Van Horn, is proving a rich producer of zinc ore. S. W. Howard, owner of the property, resumed development on it a short time ago, and he has already shipped considerable quantities of ore that settled well at the smelter. Other zinc prospects in the same locality will be opened in a short time, it is announced.

Exploration work in the Hazel mine in the Van Horn district brought to light a large body of silver and copper ore recently. This property has been on a producing basis for some time.

William Crosby and R. R. Foster are preparing to develop a deposit of tungsten ore which they recently discovered in the Quitman mountains, south-west of here.

J. A. Johnson and associates are installing machinery preparatory to opening up a copper mine on Canal creek, in Foard county, near Crowell. It was in that same locality that George B. McClelland and associates operating under the name of the Grand Belt Copper Co. built a smelter to treat the copper beds in 1884. The company spent about $500,000 in prospecting and development, and then abandoned it all because it was found to be unprofitable.

Alpine, May 17.

UTAH

Boxelder County

At the Lakeview Mining Co.'s property at Promontory 90 men are employed. Heavy shipments of zinc ore are made regularly. The southern part of the mine will become a large lead producer. The main adit is in 1200 ft. Lessees are employing 50 men. The district is thriving, and new companies are being formed.

Juab County

The Tintic Milling Co. is to enlarge its plant to three times its present capacity of 100 tons per day. The leaching capacity is 300 tons. Six new roasting-furnaces will be erected.

Piute County

The Mineral Products Co.'s potash plant at Marysvale is not giving entire satisfaction. New machinery is to be installed to overcome the trouble. At present 115 tons of ore is treated daily, yielding 15 tons of potash by the Chappell roasting and boiling process. A sulphuric-acid plant is being added. G. T. Jones is in charge. At the mine the adit is in 1000 ft. in a good grade of alunite, up to 40 ft. in width.

The Florence Mining & Milling Co. of Philadelphia, near the Mineral Products Co., has purchased a mill-site. The proposed plant will treat 100 tons of alunite daily, yielding 12 to 15 tons of potash.

Summit County

East of Clayton's peak, near Park City, the Daly Judge Extension Mining Co. has commenced work at a depth of 90 ft. A 700-ft. adit has also been driven. Prospects are said to be good.

Daily shipments from the Silver King Consolidated are 60 tons of $50 ore. Development and production is under way at 1800 ft. Machinery for a 10,000-ft. aerial tram and 500-ton mill has been ordered.

WYOMING

Park County

Extensive deposits of sulphur have been developed by the Midwest Sulphur Co. near Cody, and its 4-ton capacity plant of refined sulphur is to be enlarged to 12 tons a day, costing $20,000. The output so far is 1800 tons of sulphur. The ore is quarried, and some contains 40%. Contracts have been made for the output at $35 to $40 per ton; normal prices are from $20 to $25.

Platte County

An extensive pocket of copper ore has been opened in the Colorado Fuel & Iron Co.'s mine at Sunrise.

CANADA

British Columbia

During the year ended April 30, 1916, the Rambler-Cariboo Mining Co., operating at Three Forks, produced 1,292,644 lb. lead, 472,871 lb. zinc, and 156,755 oz. silver, from 21,000 tons of ore concentrated. Revenue from all sources totaled $155,964. Dividends absorbed $52,500. Cash on hand amounts to $16,509. The mine is in good condition. On the 700, 800, 900, 1000, and 1200-ft. levels new shoots were opened. On June 15 there will be paid 2c. a share, or $35,000.

A small stamp-mill is to be erected at the Emancipation mine of M. Merrick and partner near Hope. A recent shipment of 3 tons to the Selby smelter netted $1591 per ton.

It is reported that the Tonopah Belmont company of Nevada is negotiating for purchase of the Queen gold mine near Salmo. Wisconsin people are the present owners. The mine is equipped with a 20-stamp mill and has been developed to a depth of 700 ft. On the lowest level the drift has been carried 20 ft. wide for more than 100 ft. in length, and the average of all the ore thus extracted was $9.50 per ton. The mill saves 60% of the value on the plates, and produces 100

tons of high grade concentrate monthly. There is an immense accumulation of tailing which will pay well when treated by cyanidation or flotation.

There are 10,000,000 tons of reasonably assured and probable ore, carrying 1.7% copper and about 20c. in gold and silver, in the Copper Mountain holdings of the British Columbia Copper Co., a subsidiary of the Canada Copper Corporation, according to Oscar Lachmund, general manager, who was recently at Spokane. The ore is all of a milling character, and the company plans to treat it all by flotation. The property is to be equipped with a 2000-ton daily capacity reduction plant. Meanwhile the company is prosecuting development of the upper orebodies that can be mined by the glory-hole system. Diamond-drilling is finished for the present, and the orebodies so disclosed are being proved by regular development. In doing this a 2000-foot tunnel is being driven, opening a set of levels with raises, installing surface equipment, and building a power transmission line 12 miles long from Princeton to the mine. About 125 men are employed. At Greenwood only one furnace was in blast until April 2, when the second and smaller one was blown-in. The company is now treating 1400 tons of ore daily, of which about 100 tons is custom ore. It has been getting a good deal of ore from mines in the United States, and could handle more, provided it is not too silicious. Coke shortage is causing some trouble.

KOREA

The Seoul Mining Co. operating the Suan concession in Whang Hai province, Chosen, reports the following results for April:

Ore treated, tons	16,432
Mill worked, days	27.7
Recovered: Bullion	$65,000
Concentrates	87,310
Total	$152,310
Expenses	57,500
Operating profit	$ 94,810

Copper is figured at 15c. per lb.

Results are a little better, owing to improved extraction at the new mill. If copper were calculated at market prices the production returns would be materially increased, since the copper equals well toward 50% of total value recovered.

The April clean-up of the Oriental Consolidated was worth $143,700.

The price of the Kapsan Mining Concession in Korea was 3,000,000 yen, equivalent to $1,500,000. The ore developed amounts to 168,000 tons of 10.5% copper ore. The Japanese appear to have made a good bargain.

MEXICO

Oil shipments from Tampico during April were 1,262,987 bbl., against 740,611 bbl., in 1915. Ocean tankage is scarce.

Jalisco

(Special Correspondence.)—A decree dated May 11 prohibits the exportation of Mexican money or its removal from the country. The new "infalsifiable" money has commenced to circulate, and is declared officially to have a value of 20c. Mexican gold, per *peso*. In Mexico City it appears to be worth about four times as much as the older paper money still in circulation; in Guadalajara about twice as much. There was a recent edict giving the value of the new infalsifiable at 20c. Mexican gold, stating that the older paper money should have a relative value to the new, as fixed by the respective State secretaries. Very noticeable about the new money is the absence of "promise to pay" of any sort, printed on them. They are well made, however, and difficult to counterfeit, being made by the American Bank Note Company.

Guadalajara, May 15.

PERSONAL

Note.—The Editor invites members of the profession to send particulars of their work and appointment. This information is interesting to our readers.

D'Arcy Weatherbe is in Russia.

H. F. Marriott is at Johannesburg.

Courtenay De Kalb is at Los Angeles.

Hon. S. Rivett was at Oroville this week.

Ernest Williams is here from British Columbia.

A. H. Wethey is working with the Red Cross in Europe.

Frederick P. Burrall, of New York, is going to the Yukon.

H. E. Colliran is on a visit with John B. Farish at San Mateo.

A. L. Clark is now in the employ of the Anaconda company at Butte.

H. Vincent Wallace, recently at New York, is now at Helena, Montana.

A. F. Kuehn is returning to London from Burma by way of the United States.

C. C. Burger was here this week on his way back to New York from Arizona.

Orvil R. Whitaker, of Denver, passed through San Francisco on his way to Arizona.

Chester W. Purington has been re-engaged as consulting engineer to the Lena Goldfields.

E. W. Mills and J. F. Manning have reached San Francisco from Korea, on their way to Boston.

F. G. Clapp of the Associated Geological Engineers is conducting geological explorations in southern Oklahoma.

W. L. Brown, D. E. Hoffmann, W. N. S. Van Diventer, and N. Waggoner have returned from the Belgian Congo and are now in London.

E. E. White, geologist for the Cleveland-Cliffs Iron Co. during the past seven years, will go to India to take a similar position with the Tata Iron & Steel Company.

E. M. Rabb, formerly superintendent of the Gold Road and Tennessee mines, both in Arizona, has resigned to accept the management of the Tom Reed mine, at Oatman.

James A. Lannon has succeeded Webster P. Cary as superintendent at the Atlas Mining & Milling Co., Ouray, Colorado. Mr. Cary resigned to take a position with James M. Callow, Salt Lake City.

Fred B. Close, who has been in charge of the exploration and development at the White Pine Extension, Michigan, has resigned, and is succeeded by William R. Bolley, who has been engineer at the property for the past year.

Leonard R. Dickerson of Chicago was found dead at Kenosha, Wisconsin, on May 16. It is believed that he fell from a train. He was vice-president of the Chicago club of Michigan College of Mines men.

The Colorado School of Mines at Golden announces the following appointments, to take effect September 1: George J. Young, now professor of mining engineering, University of Minnesota, to the professorship of metallurgy; Claude C. Van Nuys, now professor of physics, South Dakota School of Mines, to the professorship of physics; Carroll C. Dolman, now principal of the High School at Monte Vista, Colorado, to the assistant professorship of English and foreign languages; Fred G. Carter, University of Wisconsin, to be athletic director.

On June 1 the technical societies of Los Angeles, including the local sections of the national engineering organizations, met to discuss preparedness, also the formation of an engineer corps of California.

THE METAL MARKET

METAL PRICES

San Francisco, June 6.

Antimony, cents per pound	37.50
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	7.25—8.25
Platinum: soft metal, per ounce	$80
Platinum: hard metal, 10% iridium, per ounce	$84
Quicksilver: per flask of 75 lb	$72.50
Spelter, cents per pound	21
Tin, cents per pound	46
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, June 6.

Antimony: 50% product per unit (1% or 20 lb.)	$1.75
Chrome: 40% and over, f.o.b. cars California, per ton	11.00—15.00
Manganese: 50% metal, per ton	12.00
Magnesite: crude, per ton	7.00—10.00
Magnesite: calcined, per ton	25.00—30.00
Tungsten: 60% WO_3, per unit	30.00—40.00

At Boulder, Colorado, $40 is offered for 60% tungsten ore.

The U. S. Geological Survey's bulletin on fuller's earth has been issued. The average price in 1915 was $10.21 per ton.

Asbestos bulletin of the U. S. Geological Survey has been issued. The output in 1915 was 1731 tons, worth $76,952, an increase of 39%.

New York, May 31.

Molybdenum: There is a market, though a narrow one, for concentrate containing 50% and better of metal. For the low-grade, 60c. per pound is quoted; for the high-grade up to $1.15. There are but few users of molybdenum in this country, but the Germans are using it extensively in the manufacture of high-speed steel. The practice most approved is to use a small amount of molybdenum in conjunction with tungsten.

EASTERN METAL MARKET

(By wire from New York.)

June 6.—Copper is quiet, with re-sale metal irregular; lead quotations for this week are those of the A. S. & R. Co.; spelter is active and prices stronger.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
June 1	68.75	Apr. 25	65.52
" 2	64.87	May 2	71.45

April returns include the following: Anaconda, 30,000,000; Chino, 4,496,270; Inspiration, 10,122,686; Nevada Con., 7,771,681; Ray Con., 6,294,033; and Utah Copper, 11,557,282 pounds.

Kennecott has produced 40,000,000 lb. of copper from its Alaska property in 4 months.

A dividend of $10 per share is expected in July from the Mohawk company of Michigan, on account of profits during the past financial year.

Calumet & Hecla pays $15 per share on June 24. Calumet & Arizona has declared $2 per share for the quarter. An increased dividend is expected from Granby Consolidated, whose April output was 3,950,469 pounds.

Tin is steady at 43 cents.

Income of the International Nickel Co. in 1915-'16 was $13,470,106 net, against $6,713,387 in 1914-'15 (the year ends March 31). Preference dividends amounted to $534,756, the same as before; while common received $9,431,803, compared with $4,753,938. The surplus is $1,781,720, against $309,377.

Eastern Metal Market

New York, May 31

Copper, zinc, lead, tin, and antimony are inactive, and quotations for them are lower.

All that is supporting the copper market is the sold up condition of the producers. In the course of a few days the London market for electrolytic has declined £14. After today, by Government order, standard copper will not be dealt in on the London Metal Exchange. This restriction applies to tin also.

Zinc has declined steadily, and is soft, but the sellers are confident that a turn upward is near.

A reduction in the price of lead is looked for and, if it comes, it may revive domestic demand.

Tin has declined in both New York and London.

Antimony is down to 25c. per pound.

Aluminum is quiet and unchanged at 58 to 60 cents.

Manufacturing plants of all sorts are running at capacity, and have orders enough in hand to keep them busy for the remainder of this year, and numbers into 1917; but there is no denying that new orders are lighter. Business is restricted by the high prices, many building enterprises, for instance, having been postponed because of the cost of steel, brick, concrete reinforcing bars, lumber, etc. At lower prices there is much such business in prospect for the future. Ocean freight-rates are easier; this will mean a large export trade when commodity prices are lower and the domestic demand appeased. Strike troubles are less conspicuous, although demands continue to be made for the 8-hour day.

COPPER

The market is dull and re-sale lots are lower, but consumers do not appear to want more copper than they have under contract. Two or three facts stand out strong in the situation, and one of these is that despite some recession the market remains fairly firm, which it would not do were the producers not so well sold-up for the next few months. Another phase of the situation is that for some time consumers have been buying only to cover contracts actually booked, and the fact that they have not been buying lately is an indication that they are receiving less new business. Producers have been holding to their quotations and not offering concessions. Second-hands, however, have sought business at cut prices, but so far unsuccessfully. Large quantities have been offered, as stated a week ago, down to 28c., third quarter delivery, and bids under this figure have been solicited. Prompt electrolytic can be had at 28.25 to 28.50c. These prices indicate the extent to which the quotations for prompt and future deliveries have drawn together in the past month. The London market is peculiar, inasmuch as the electrolytic quotation there today is £144, against £158, May 24, a decline of £14. One explanation of this drop in price is that American electrolytic has been more freely offered in the London market, but the real explanation may be elsewhere. It may be that the London market is re-adjusting itself to the condition that will prevail after today. It will be remembered that in March the British Minister of Munitions took steps to stop speculation in the metals on the ground that such operations were causing the Government to pay too much for copper, tin, etc. At that time a committee of the London Metal Exchange appealed for leniency, and the Minister agreed that operators might have until June 1 to terminate speculative contracts. This means that after today (May 31) standard copper and tin will not be dealt in on the London Metal Exchange; that business will be in electrolytic copper and Straits tin. Just what effect the enforcement of the rule will have is yet to be determined. Exports from May 1 to 29 totaled 14,662 tons.

ZINC

This metal has steadily pursued a downward trend both here and abroad. Prompt can be had today at about 13.75c., New York, and 13.50c., St. Louis, and perhaps these nominal prices might be shaded, but no one seems to want the metal. June is quoted at about 13c., St. Louis, July at 12.50c., and third quarter at 12c. As with copper, the mills have their contracts well covered, and the dearth of new business is not only sending prime Western down, but causing the premium for brass-mill special to disappear. Exports for 29 days totaled 3746 tons. The London market, between the 26th and 29th declined £10, from £90 to £80. A seller states:

"Once the market starts up, a higher range of values will likely prevail for some time. Present low prices have been brought about by an entire absence of buying both here and abroad. The consumption is, of course, as large as ever and we expect a better demand in the near future. More interest is already manifested. The situation remains sound, and prices will advance with the first sign of renewed activity."

The base price of sheet zinc declined 2c. on the 29th, and is now 22.50c., carload lots, f.o.b. mill.

LEAD

The A. S. & R. Co., for the purpose of obtaining a basis for its average price, continues to quote 7.50c., New York, and 7.42½c., St. Louis, but the independent producers and sellers are eager to sell below these levels. They quote freely at 7.35c., New York, and would not refuse 7.25c., New York. It is reported that 7.10c. and 7.15c., St. Louis, has been done. The feeling of the trade is that prices will be reduced in the near future. Domestic consumers are no more anxious to buy lead than they are to take the other metals, and sellers have concentrated their attention on some inquiries from Japan and South America which have been before the trade. It is considered, however, that the business did not come to this country. The London quotation on the 29th was £31 10s. Exports to the 29th totaled 1025 tons.

TIN

Only dullness is to be reported. At times the offering of price concessions has aroused consumers from their apathy, and there have been moderate-sized sales, but the buyers usually were sorry afterward, in view of the fact that prices continued to recede. The quotation on the 29th was 46.75c., for spot metal. The London market in the first three days of this week declined £5 10s., probably as a result of the termination of speculative contracts with the end of this month, and the refusal of the British government to permit a continuance of such business. Arrivals of the month up to the 29th totaled 3812 tons, and there was afloat on that day 3502 tons.

ANTIMONY

Quotations show considerable variance, but there is no doubt about the acceptance of 25 to 26c. for round-sized lots of Chinese or Japanese, or domestic brands of antimony. The market is absolutely neglected. No trading whatever in needle antimony is reported.

ORES

Antimony: Considerable inquiry is before the trade, but no sales are reported, and the nominal price is $2.50 per unit.

Tungsten: The market is perhaps a little steadier, but otherwise unchanged. Some re-sale lots have made their appearance, and the course of prices cannot be certain until they are absorbed. No ore has come from South America for several weeks. The nominal price is $40 per unit.

COMPANY REPORTS

RAND MINES, LIMITED

This company holds shares in over 20 operating companies on the Rand, including the City Deep, Crown Mines, East Rand Proprietary, Ferreira Deep, Geldenhuis Deep, Modder B, Nourse, Robinson, Rose Deep, Village Deep, and Victoria Falls & Transvaal Power Co., all totaling an investment of £4,091,345. Dividends received on shareholding amounted to £868,539, while other revenue made a total of £927,213. The profit was £886,356, a decrease of £279,895, due to less dividends received. Dividends paid by the Rand Mines (2 of 160%) amounted to £850,398. The balance for the current year is £320,289, against £339,103 carried forward to 1915.

Ore reserves in the mines in which this company is interested total 47,773,430 tons.

NORTH BUTTE MINING CO.

The past three years of this company compare as follows:

Operations	1915	1914	1913
Development, feet	15,333	11,551	19,449
Ore extracted, tons	378,105	337,415	454,984
Copper produced, pounds	19,235,285	18,421,761	28,318,321
Gold produced, ounces	1,122	1,108	1,567
Silver produced, ounces	940,632	1,092,300	1,422,177
Price received for copper, cents	16.70	13.74	15.09
Cost, cents	13.12	14.54	13.06
Revenue from metals	$ 4,155,522	$3,084,774	$5,182,674
Profit	1,127,646	358,215	1,437,777
Dividends	387,000	635,000	820,000
Surplus	$ 740,646	*$276,785	$617,777

*Deficit.

All new equipment at the Granite Mountain shaft was completed in 1915. This has an electric hoist, while the Speculator has a steam plant. Development generally was satisfactory, and much new ore disclosed.

BROKEN HILL SOUTH SILVER MINING CO.

The report of this Australian company is for the half-year ended December 31, 1915, and the manager's (W. E. Wainwright) notes include the following:

Development to a depth of 1370 ft. totaled 6913 ft. Depleted stopes were filled with 43,730 cu. yd. of residue and ash. Of the ore stoped, 95.3% was by contract, the miners averaging $3.84, and the trammers $3.24 per 8-hr. shift. Results were satisfactory, and reserves remain at 3,350,000 tons. The cost of ore extraction was $3.20 per ton.

The concentrating plant treated 164,210 tons of ore assaying 14.6% lead, 7.5 oz. silver, and 14.8% zinc, yielding 30,658 tons of concentrate containing 60% lead, 23.6 oz. silver, and 9.9% zinc. The recovery by water concentration was 76.6%, 58.9%, and 12.5% respectively, at a cost of 96c. per ton. The zinc-bearing tailing, amounting to 101,044 tons, assaying 17.3% zinc, 3.1% lead, and 3.4 oz. silver, was sent to the Amalgamated Zinc (De Bavay's) flotation plant. The recovery from this was 71.8%, 12.9%, and 27.9% respectively. The total recovery was 89.5% lead, 86.8% silver, and 94.3% zinc. A flotation plant is ready to treat the slime, which contains 9.9% lead, 6.1 oz. silver, and 14.4% zinc. All costs were $5 per ton.

An average of 1287 men was employed. A voluntary increase of 24c. per shift was paid the men, pending arbitration. The rainfall was 5.49 in. The company has lent three lathes for making gun shells for the Australian army.

The revenue was $1,730,000, and profit $913,000. Two dividends absorbed $432,000. The balance for 1916 is $1,872,000, an increase of $320,000.

CALUMET & HECLA MINING CO.

The 82-page report of this Michigan company for 1915 includes results of its own operations, and those of the companies which it controls or has a large interest. These include the Ahmeek, Allouez, Centennial, Cliff, Gratiot, Isle Royale, La Salle, Laurium, Osceola, Seneca, Superior, Tamarack, White Pine, and Calumet Transportation companies. Some of their reports have already appeared in this journal; others will in subsequent issues. During the past year the C. & H. received a total of $866,776 from the Ahmeek, Allouez, and Osceola, compared with $245,322 in 1914. The following results are for the past year:

	Copper per ton of ore lb.	Cost of copper per lb. cents	Earnings per share	Dividends per share
Ahmeek	23.00	7.96	$11.34	$8.25
Allouez	18.78	9.31	9.25	2.00
Calumet & Hecla	22.28	9.33	65.54	50.00
Centennial	15.63	12.45	1.58	....
Isle Royale	13.70	*14.94	3.32	....
La Salle	9.67	21.23	....	....
Osceola	14.50	10.03	16.75	11.00
Superior	18.23	12.29	2.45	....
Tamarack	17.90	17.07	1.32	....
White Pine	24.76	†14.44	....	....

*Includes 1.88c. per lb. for extraordinary construction.
†Includes 5.64c. per lb. for construction.

On the Conglomerate lode of the C. & H. there are 10 operating shafts, from 6102 to 8132 ft. deep on the incline. The South Hecla No. 9 and 10 are 142 ft. under No. 82 level. Driving on this lode amounted to 5522 ft. In extracting 1,739,984 tons of ore, containing 29.74 lb. of copper per ton, the cost was $2.13 per ton. There were 51 drills removing shaft pillars, and cleaning-up arches and backs of old stopes, producing 379,201 tons. Shafts on the Osceola lode are from 1460 to 3274 ft. deep. Development covered 10,206 ft. At a cost of $1.07 per ton, 1,448,599 tons of ore, averaging 13.32 lb. per ton, was mined.

There were no notable changes at the mill. At present 17 stamps are crushing conglomerate and 11 amygdaloid ore. The two re-grinding plants reduced 505,704 tons of tailing, averaging 13.14 lb. copper per ton. The saving was 4.25 lb. at a cost of 5.72c. per lb., excluding smelting and selling. The reclamation plant, working on the Calumet sand bank, consists of a dredge, classifying house, and re-grinding plant. The dredge has a 20-in. suction, and is of 10,000-ton daily capacity, from a depth of 100 ft. Forty-eight Hardinge mills reduce the talling, with 16 to be added. The reclamation plant treated 181,732 tons of 21.8-lb. tailing, saving 8.71 lb. at a cost of 4.02c. Work continues at the leaching plant, which may be in part operation early this summer. It will be of 2000 tons' capacity. At the Hubbell smelter the new furnace is about ready for work.

Results in 1915 were as follows, compared with the previous two years, the figures being for C. & H. proper.

	1915	1914	1913
Ore treated, tons	3,188,583	2,592,462	2,035,625
Refined copper produced, pounds	72,613,320	53,691,562	45,016,890
Refined copper per ton of of ore, pounds	22.28	20.70	22.11
Cost, cents per pound	9.33	11.35	14.25
Price received, cents per pound	18.11	14.01	15.77
Dividends paid, per share	$50	$10	$32
Dividends paid, for year	$5,000,000	$1,000,000	$3,200,000
Total to date	$129,250,000		

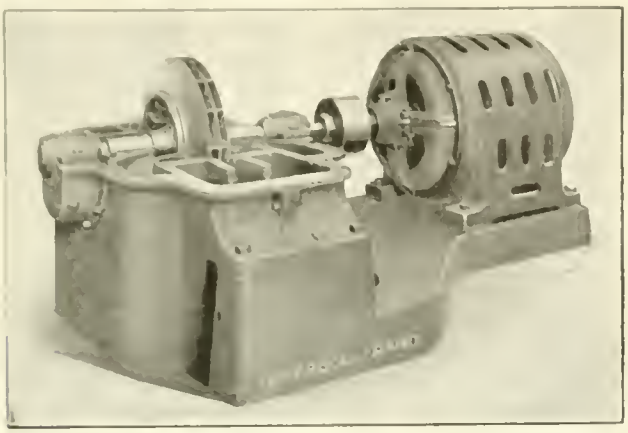
The Tamarack mine has been purchased; a large majority of the stockholders sold their shares to Calumet & Hecla for $59 per share.

INDUSTRIAL NOTES

A New Turbo-Blower

A low pressure turbo-blower to deliver from 3000 to 35,000 cu ft of air per minute at from 1 to 2½ lb. has been devised by the Ingersoll-Rand Company.

These machines are particularly adapted to such service as foundry-cupola blowing, atomizing oil for oil-burners, supplying blast to heating and annealing-furnaces of various kinds, blowing air for water-gas generators, pneumatic conveying,



NEW TYPE OF TURBO-BLOWER.

and ventilating. They are of the single-stage, double-flow type, and are supplied either electric motor, steam turbine, or water-wheel driven. Electric drive is generally employed for the classes of service above mentioned, and in the case of the I-R turbo-blower, the high operative speed permits direct coupling to motor, a first cost economy. The motor-driven I-R machine maintains constant pressure, while delivering any volume from zero to maximum demand, and proportionately varying the electrical horse-power input.

These blowers embody the four-bearing construction featured in all turbo machines of this make. The casing is horizontally split for ease in installation and subsequent inspection. The impeller is of the enclosed double-flow type, claimed by the manufacturer to secure the highest efficiency. The wheel is machined from a solid, special steel forging. Every care is taken to reduce skin-friction. Impellers are keyed to a heat-treated forged-steel shaft. Labyrinth packing is employed to prevent leakage between impeller and casing. Bearings are ring-oiled, and both bearings and their housings are horizontally split. The use of flexible couplings between blower and driving unit is standard practice on all I-R turbo-blowers. Machines are all of the closed intake type. The intake opening is at the bottom and discharge at the top. It is to be noted that the only lubrication necessary is that of the bearings, all other parts working without friction.

The 'Meeseco' gas-engine clutch (Bried patents, issued and pending) a new friction-clutch for gas-engine or short-shaft work, is described in Bulletin No. 5-15-16 of the MEESE & GOTTFRIED Co. of San Francisco. For its size great power is claimed. It is made in two styles; one in which it is bolted to an engine fly-wheel when there is no projecting shaft, and that where it is attached to a projecting shaft.

The OLIVER CONTINUOUS FILTER Co., San Francisco, has received an order, by cable, for two filter units, each of 150-tons capacity, to be shipped to the Furukawa Mining Co., Tokyo, Japan.

EDITORIAL

T. A. RICKARD, Editor

AMONG war supplies a great increase of export is noteworthy in brass, of which $27,725,470 was exported in March this year, as against only $2,749,835 worth in the corresponding month of 1915—a tenfold increase. Copper exports have risen from $9,995,487 worth in March 1915 to $18,409,615 in March this year—a doubling of foreign business. The larger part of this trade in copper was with France.

FOUR of the greatest zinc-producers in the country are the New Jersey Zinc, Butte & Superior, Consolidated Interstate-Callahan, and American Zinc companies. It is a curious fact that the first named has its chief mines within 50 miles of New York city, the second is situated in a district famous for copper, the third in a region known principally for its lead-silver mines, while the fourth obtains its ores from eastern Tennessee, which is best known as a mining region through the productive activities of the Tennessee and Ducktown copper companies.

DEFICIENT postage on a letter is not conducive to business. An engineer writes to us from Salvador to remark that many people in the United States seem unaware that the postage to Salvador from this country is 5, not 2, cents. If less than the requisite stamp is put on the letter, then the party to whom it is addressed has to pay a fine of 30 centavos, which, at the current rate of exchange, is equivalent to 11 cents U. S. If the letter is from a friend the impost is paid without demur, but if it proves to be a circular the fine irritates. Such an oversight on the part of business houses is likely to cause loss of trade, for a merchant is not in the best frame of mind to prepare a repeat order after he has had to go to his petty cash. These remarks apply to correspondence with persons in other foreign countries, of course. Every office should consult the Postal Guide and avoid unnecessary blunders.

IT is a coincidence that the Nevada Consolidated and Calumet & Hecla companies mined nearly the same tonnage of ore last year. Each treated slightly over 3,000,000 tons, the recovery by the Nevadan company being 21.6 lb. of copper per ton, that of the Michigan company 22.28 lb. per ton. One extracts its ore, native copper disseminated in conglomerate and amygdaloid, by means of underground mining through shafts; the other mines chalcocite disseminated in monzonite porphyry, using steam-shovels in open pits. Calumet & Hecla paid $5,000,000 in dividends, while Nevada Consolidated paid $2,999,158, the former having 100,000 shares outstanding, the latter 2,000,000. Incidentally, the Chino mine in New Mexico produced more copper last year than Nevada Consolidated, 68,293,893 lb. as against 62,726,651 lb., from a smaller tonnage of ore, 2,379,800 against 3,081,520 tons. This was possible because of Chino's 2.15% average against Nevada Consolidated's 1.54% of copper.

RECOGNITION of the fact that industrial conditions are abnormal prevents heavy commitments for the future. Such over-buying as is evident has been prompted by rising prices and the fear of a shortage of the necessary supplies. Nobody cares to be left with heavy stocks when Peace brings a re-adjustment of conditions. Construction work is being delayed by the high cost of metals, but postponement cannot continue indefinitely, particularly in railroad improvement. The revenues and tax-receipts of the Government exhibit an enormous increase, reflecting the growing wealth of the country.

WHEN publishing the diagram illustrating the sequence of metallurgical operations at the International smelter, at Miami, in our issue of June 3, we should have explained that the ore contains no more sulphur than is needed; therefore the drying is conducted at a temperature at which volatilization is at a minimum. This accounts for the rather low tonnage treated by the reverberatory furnaces, since the charge, compared with that at other plants, is rather cool and lacks the advantage of such incipient fusion in the roasters as increases the rate at which the calcine will smelt. The reverberatories are charged, exclusively, at the sidewalls. About 82% of the concentrate is the product from flotation. The recovery of copper for the last four months has averaged 97.3% and the manager of the smelter, Mr. L. R. Wallace, expects to attain 98%. In March the production of bullion was 8111 tons.

HIGH-GRADE copper ore is not so common in the West as formerly. Aside from the Jerome district in Arizona and the remarkable 60% ore of the Kennecott mine in Alaska, the Calumet & Arizona and the Old Dominion furnish the best examples of the mining of high-grade copper ore. The Calumet & Arizona company, it is scarcely necessary to recall, operates mines at Bisbee adjoining the Copper Queen property of Phelps, Dodge & Co. The ore mined by the Calumet & Arizona during last year averaged 98 lb. of copper per ton, or nearly 5%. From 664,152 tons of ore mined, the production was 63,126,931 lb. of copper, an output equal to that of the Chino, Ray, or Nevada Consolidated. By way of comparison, the Isle Royale Copper Company, in Michigan,

one of the lowest grade producers in the country, mined a greater tonnage of ore than the Calumet & Arizona, but produced only 9,312,106 lb. of copper, because the content of the ore was but 13.7 lb. per ton, or 0.68%. The Old Dominion company, which operates very wet mines at Globe, also mined ore of an average grade of nearly 5% copper during last year. From 256,699 tons of ore mined, 25,307,702 lb. of copper was produced. This is more metal than the Quincy mine, in Michigan, produced from 1,269,000 tons of ore. We note that the report of the Copper Queen Consolidated for last year states that "the grade of ore in five of the six producing divisions is only 5.36%, but that of the sixth is 7.27%, which raises the average to about 6% copper." The Copper Queen mines produced last year 93,900,000 lb. of copper. Among recent developments the most remarkable is the orebody in the United Verde Extension, at Jerome, where a mass of ore 250 feet square averaging 17½% copper has been uncovered, with the happy result that a number of technical men, among the shareholders, have been made independent.

DISCUSSION this week starts with a letter by a Nevadan metallurgist, Mr. Alfred M. Smith, on the heating of cyanide solutions, arguing that the use of heat is dangerous unless applied carefully and with an understanding of the chemical results that may ensue. Mr. F. C. Brown, the inventor of the Brown agitator, erroneously called the Pachuca tank, writes on a matter quite divorced from cyanidation, namely, the advisability of working on Sundays. He quotes from a book that is not always to be found in the library of the engineer when away from home, but which no thinking man can treat save with profound respect. The tone of his remarks does honor to our columns. In these days when efficiency is being preached as if it were a recent revelation from on high, it is well to consider the question of Sunday labor as a factor in promoting the good health of employees. Every man who works is entitled to his own opinion on the subject, and not the manual laborer only. Our own experience as manager of mines goes to show that men will accomplish as much in the six days as in the seven, and that uninterrupted daily labor is broken eventually by staleness or illness. This applies to the technical staff on a mine just as much as it does to the trammer or the roustabout. Of course, the economy of interruption on Sundays may be lessened where a mine is extremely wet or where otherwise the cost of maintenance or the overhead charge happens to represent an excessive proportion of the total expenditure. Now that prohibition is established in so many mining communities the danger of the Sunday 'drunk' and the Monday reaction has been lessened appreciably. That used to be a decided objection to closing-down on the Sabbath, the argument being that it hurts a man less to over-work than to over-drink, as to which there is good reason for doubt. However, we feel assured that Mr. Brown's letter will be given friendly consideration. Next we have a contribution on Chinese mining regulations by Mr. M. B. Yung, whose name suggests the fact that he is a Chinese engineer technically educated in the United States. Therefore he writes from a point of view particularly desirable on a subject involving Chinese rights and American desires. 'Put yourself in his place' is a good motto for those of us who discuss the exploitation of mines in foreign countries. Imagine Chinese syndicates claiming the right to mine along the Mother Lode or on the Copper Range, and consider what latitude you would think it proper to give them in their operations. What is sauce for the goose is sauce for the gander. Mr. Yung's comment is eminently reasonable. The last letter in the Discussion department is one from our Mr. P. B. McDonald, who discusses the character of the literature, ephemeral or classic, as the case may be, that mining men read. He is rightly contemptuous over the daily press, for he has in mind not the newspapers of New York but those that prostitute journalism in San Francisco. The reading of these debauches the mind and dulls the wit. We agree with him that those living in remote localities are saved the temptation of reading much that is merely trivial. Young men on solitary mines or in places where company is scarce will be wise to make the most of their detachment from social activities by reading books that are worth while. If a young man does not read the masters—such as Huxley and Darwin—and the monographs—such as Emmons's 'Leadville' and Lindgren's 'Tertiary Gravels,' during the time of his apprenticeship, he is likely not to read them at all; for they demand time and quiet. We know at least one mining engineer who was marooned at a hole in the ground long enough to obtain the chance, while on salary, to read several volumes the bulkiness of which would appal a busy man. In short, use the opportunity to read and thereby lay the foundation for an enrichment of the mind that will endure.

Zinc

The price of this metal is declining in value for reasons not in the least obscure, namely, excess of production prompted by the high prices created by War conditions. At the beginning of 1915 the price was 5½ cents per pound; last June it was 27; now it is 13. Producers are sold several months ahead. For a short time concentrate containing even less than 40% zinc could be exploited at a profit, owing to the abnormal demand; the expansion of the market caused hundreds of new producers to become active, prompting the erection of additional smelters on a liberal scale, until the growth of production had more than met the unusual demand. Several new reduction works will shortly come into operation. The Allies were expected to buy large quantities of spelter for the second half of the current year, but these purchases have not come through; hence the recent collapse. Meanwhile the Australian zinc industry is being reorganized to meet conditions created by the War. The output from Broken Hill in 1913 was 525,000 tons of 45% zinc concentrate, as compared with the 337,000 tons of spelter produced in this country during the same

year. Most of the Australian concentrate used to go to Antwerp and Rotterdam, for distribution among the Belgian and German smelters. The Belgian plants were largely under German control and the German smelting companies had been aided in the expansion of business by ship-subsidies from their Government. At the outbreak of hostilities, therefore, the Australian zinc industry found itself in the grip of an enemy. All shipments ceased and there arose talk of building reduction works in England and Australia, but existing contracts with the German and Belgian smelters paralyzed action. In August, 1915, the Commonwealth government passed a bill cancelling contracts with enemy-aliens, and thereby cleared the way for the Associated Smelters, a consolidation of mining interests at Broken Hill organized to treat the lead and zinc output from that district, starting with the Broken Hill Proprietary works at Port Pirie as a nucleus. The only companies not included were the British Broken Hill Proprietary and the Zinc Corporation, both of which were registered in England and were tied by German contracts that were not released by the Australian enactment: another exception was the Sulphide Corporation, which owns the Central mine at Broken Hill, and controls both the Central zinc smelter near Newcastle, in England, and a lead smelter at Cockle Creek in New South Wales. All the efforts to organize a new and big reduction works in England were blocked by German contracts, which the British courts were slow to set aside. However, in September 1915 a beginning was made by the transfer of the small smelter at Swansea Vale in South Wales, from Aron Hirsch & Sohn of Halberstadt to a syndicate headed by Messrs. H. C. Hoover and F. A. Govett, representing a group of financiers identified with the Zinc Corporation and the Burma Mines. Finally, on May 12, 1916, the British government made an order 'determining' the contracts made in 1910 and 1912 between the British Broken Hill Proprietary Company and the Zinc Corporation on the one side and German smelters on the other. At about the same time the Sulphide Corporation made an arrangement, with the British government's sanction, to purchase the Central Zinc Company's plant in England and enlarge it to a capacity of 30,000 tons of concentrate per annum. Furthermore, it is announced by the *Financial Times* that the directors of the Zinc Corporation have definitely decided to erect a smelter of their own in England, at an expenditure of $10,000,000, unless the Commonwealth government extends its embargo on the export of concentrate to companies of English register, as is not likely. Meanwhile the interests tributary to the Associated Smelters have organized a Zinc Producers Association, making provision for the marketing of their united output during a period of 50 years. Arrangements with the Vieille Montagne company, with a view to protecting the Belgian zinc-smelting industry, are also likely to be made, as part of the industrial alliance between England and France. All of which is here recorded to make clear the fact that the Australian zinc industry is to be placed on its feet again and therefore in a position to contribute, say, 250,000 tons of spelter per annum.

The mention of the Burma Mines is significant, for that company has uncovered an orebody at Bawdwin, in the Northern Shan States, that promises to be a factor in the zinc market. Already 2,000,000 tons of ore averaging 22½% zinc, besides 27% lead, and 25 oz. silver per ton is said to be assured, with excellent prospects of a big increase of tonnage as development proceeds. It is not necessary to remind our readers how mines in the copper and lead districts have begun to contribute a large quota of zinc, for example, the Butte & Superior and the Interstate-Callahan mines; indeed zinc, in the form of blende, is a by-product of most metal-mining operations in the West. Hitherto blende has been regarded not only as a sign of deterioration in lodes valuable for their gold, silver, lead, or copper, but commonly it has been an excuse for smelter penalties of a drastic kind. It is not too much to say that blende has been regarded as a nuisance both by the miner and the metallurgist. Unquestionably this mineral is widely distributed and can be won at an accelerating rate of production if the demand is maintained. No natural monopoly of it exists, so that over-production is inevitable unless the price drops severely. That, of course, is a logical consequence of easily recognizable conditions. The price was 5 cents before the War; it is 13 cents now; a compromise between these extremes is certain. "The world of economics balances on the thin edge between 'must have' and 'must sell'." We expect to see a thriving industry maintained with spelter at about 7 cents per pound.

Enrichment of Copper Ore

In this issue we give our readers the third of Mr. Probert's articles on the 'Surficial Indications of Copper.' On this occasion he discusses the chemistry of the oxidized zone and attacks problems of the greatest scientific interest. In the course of his analysis of the chemical and physical factors at play in the uppermost portion of copper deposits, he makes us pleasantly aware of the recent growth of knowledge on this obscure subject. It seems long ago since Emmons, Winchell, and Weed started the train of investigation that explained to the miner how copper migrates from one part of a lode to another and how it is arrested in that migration so as to compose rich orebodies. We know all about secondary enrichment now, at least until we try to state what we know in plain words, when we possibly discover sundry voids in our understanding of the chemical reactions, which are necessarily complex. The experiment made by Mr. Horace V. Winchell, in 1902, whereby he made chalcocite synthetically by the action of copper sulphate on pyrite in the presence of sulphur di-oxide, was illuminating, even if it be granted that the presence of sulphur di-oxide in descending waters is uncommon. Mr. H. N. Stokes showed by another experiment that a neutral solution of cupric sulphate will react with pyrite so

as to precipitate chalcocite. And while we have learned now that all chalcocite is not of secondary origin, we have abundant proof of the fact that many important orebodies enriched by that mineral, together with covellite and bornite, are the result of such a process, as is the case more particularly in the disseminated copper deposits to which Mr. Probert directs our attention in his articles. In the arid regions of the Great Basin, between the Rocky Mountains and the Sierra Nevada, the factors of temperature, depression of the ground-water level, and porosity of the surface to carbonated waters have been potent in facilitating the leaching of outcrops. To this has been added the effect of relatively slow erosion as compared, for instance, with the Arctic or other regions exposed to planing by ice-sheets. This point was elucidated by Mr. Winchell, many years ago, to explain the scarcity of secondary sulphide enrichments in the North. It is hardly necessary to remark that an apparent exception, namely, the remarkable mass of chalcocite ore at the Bonanza, or Kennecott, mine in Alaska, is conceded by Messrs. L. C. Graton and C. F. Tolman to be primary. Among other notable enrichments, the Chuquicamata, in the high arid region of Chile, is unique in consisting chiefly of brochantite, the basic sulphate of copper, a relatively rare mineral frequently confused with atacamite and formed probably by the oxidation of chalcocite, as suggested by Mr. Waldemar Lindgren. How great a range of reactions is involved in the chemistry of copper ores is indicated by the series of equations quoted by Mr. Probert. Of course, these express only the dominant exchanges; between them come innumerable modifications and interplays quite beyond expression by any formula, and complicated, as such reactions always are in nature, by the volume of water that serves as the medium wherein they exercise their multitudinous activities. Lots of water and plenty of time must always be conceded in any attempt to follow the operations that culminate in a deposit of ore. All of which is made clear in Mr. Probert's admirable essay, wherein he also brings out the significance of cuprite, and native copper, as an indicator of the second cycle of oxidation by descending waters of surficial origin. Yes, indeed, the earth's attic, called the 'crust' by geologists, is a laboratory in which experiments on a large and conclusive scale are ever at work.

A Box of Cigars

Gratitude is defined as a feeling of appreciation for favors shown, or expected. Walpole said that "the gratitude of place-expectants is a lively sense of future favors." Dr. Johnson considered gratitude a fruit of great cultivation not to be found "among gross people," and as he made the remark while touring in the Hebrides we presume he was not feeling very well. Like most good things, gratitude can be overdone. "Thank me no thanks" exclaims one of Shakespeare's characters. "To be over-thankful for one favor is in effect to lay out for another." More true, however, is the saying of Benjamin Franklin: "He who has once done you a kindness will be more ready to do you another than he whom you yourself have obliged." Men like to forget those to whom they are under obligation, especially if they are conscious of having failed to reciprocate, while the generous man loves to repeat his kindness to one who has shown a just, not excessive, appreciation. An excess of gratitude is unpleasant, it becomes confused with servility, it is found in dogs. Man's inability to express sentiment graciously makes him an awkward animal; to most of our species the dog can give points in showing thankfulness and remembering kindness. "The winter wind is not so unkind" exclaims King Lear "as man's ingratitude." But with the average human the failure to express the feeling is due to diffidence, to awkwardness, to a desire to do it fittingly, if at all. "Thanks, the exchequer of the poor" says Shakespeare. Sincerity of feeling and naturalness of expression do not flourish among the spoiled portion of human kind; there words become counters and frankness is taboo, or *tapu*, as the Maori says. And words, at best, are but empty thanks; so, many avoid them, hoping chance may give them a better means. Our own profession, for instance, nomadic as it is, is the beneficiary of courtesy and goodwill from those whom we may meet only once. The chance to reciprocate does not offer itself, only grateful acceptance—and the resolution to pass it on, to do a similar kindness to those that, in like manner, can make no return. This is a working philosophy, at least. The ledger of hospitality—of the mind, no less than of the house—is not kept too precisely; it calls for an easy bookkeeping; it discards mean details; yet in the life of a broad-gauge man the two sides of the account will strike a rough balance, with a margin in favor of credit. In youth the account is on the debit side, for the young man receives kindnesses that he cannot hope to return; but as life matures there comes the frequent opportunity to pay back to a new generation the debt accumulated to that which preceded. Yet, it is unwise to leave much to the future. The young man should never miss a chance to express thanks to his helpers. If somebody recommends him for an appointment, if another gives him a valuable hint, if a useful warning is tendered, it is well to recognize the service. *Bis dat qui cito dat.* Engineers do favors for each other. Acknowledgment is often lacking, sometimes because the spirit of the act is less appreciated than the tangible result. For instance, one man passes a professional engagement—the inspection of a mine, for instance—to another. It is curious how many waver between the grossness of a commission and the inanity of a mere 'Thanks.' Does not the island of Cuba furnish a means of adequate expression. "In the far savannahs a talisman grows that makes all men brothers," says Lewis Morris. The fragrant product of the *vuelta abajo* is more expressive than many words. Assuredly the choice leaf of tobacco, rolled in pleasing shape, is the proper medium for transmitting just that feeling of civilized gratitude that words or money alike fail to convey.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Heating Cyanide Solution

The Editor:

Sir—In view of the fact that some small cyanide mills recently coming under my observation are heating the mill-solution by means of circulating it through an envelope surrounding an extension of the exhaust-pipes of gas-engines, it may be well to call attention to extraction and solution troubles that may result from overheating under such conditions.

The heating of cyanide solution with a view to accelerating and increasing extraction by cyanidation was investigated at an early date by cyanide operators, and to most of those who have carefully looked into the matter it is evident that nothing is gained by heating cyanide solution above the temperature of normal summer weather. When the solution is heated above this temperature, a destruction of cyanide takes place and also a re-precipitation of some dissolved gold and silver. This is due to the increased chemical activity of both the cyanide and the caustic alkali, which attack the base elements of the ore, especially the sulphides, decomposing a part of them, charging the solution with deleterious salts, especially those of sulphur. While it is stated on good authority that the increased decomposition of the bases in the ore may result in liberating "locked up" values, and so facilitate their dissolution, I have invariably noted a poorer extraction of both gold and silver in laboratory-tests when the solution was heated much above normal.

I have on record the tabulated results of hot cyanide-solution tests made on ores from Guacimal and Tres Amigos, Costa Rica, and from four different Nevada ores, and in each case a diminished extraction and increased cyanide consumption is to be noted where the temperature exceeded 120°F. This may be explained, as regards poor extraction, by assuming that dissolved gold and silver are precipitated in the pulp by base compounds developed by excessive heating. It is probable that the hot alkaline solution, caustic lime and soda being present, decomposes sulphides to form alkaline sulphides Na_2S and CaS, which in turn precipitate silver and some gold from weak solutions. This theory is supported by the fact that I have found thiocyanate present in the solution after such tests, although new solution was used at the start, and that I found no appreciable amount of thiocyanate present when the test was made with cold solution on the same ore. The increased consumption of cyanide in the hot tests is due to its active combination with base elements, and to a tendency to polymerize and decompose in such combination.

In heating solution by means of circulating it in contact with the exhaust-pipe of a gas-engine, if the solution is not rapidly circulated in sufficient quantity, it becomes heated almost to the boiling-point, as I have observed. This may result in a loss of cyanide and foul solution, especially if the solution bears considerable protective alkali. In addition to this, the solution, by such heating, is deprived of its dissolved oxygen, which is so essential in dissolving gold and silver. While the moderate warming of very cold solutions is beneficial in shortening the time of treatment, heating above normal is harmful.

If in extremely cold weather it is deemed necessary to warm mill-solutions, it should be done in such a manner that it does not necessitate a small constantly circulating quantity of solution being excessively heated in order to bring up the temperature of large quantities of solution.

ALFRED MERRITT SMITH.

Reno, Nevada, May 28.

[From his letter it would seem as if Mr. Smith has not followed the work at Tonopah, at the Mexican mill on the Comstock, and other silver districts, where a distinct advantage is gained by heating solutions to as high as 120° F. The reactions given by Mr. Smith may take place, but at Tonopah the increased recovery greatly over-balances the cost of heating solutions and loss therefrom. We would like to hear the latest results from this phase of cyanidation from our Nevada friends. The term "re-precipitation" as used in this letter has been superseded by "premature precipitation." —EDITOR.]

Sunday Work at the Mines

The Editor:

Sir—Most subjects pertaining to mining come under discussion in your valuable journal, but although I have been a regular reader for many years, I do not remember coming across any views for or against Sunday work in mining.

It seems to me that in the Western States the custom of operating mines and mills on Sunday, just the same as on any other day, has become so universal that if anyone were to raise his voice against it, he would be considered either a crank or one who had not the interest of the industry at heart. But yet, just because a thing is the custom, it does not necessarily follow that it is

correct, nor the best for all concerned. In matters pertaining to the human family, like the one day's rest in seven, one naturally turns to the Bible for information, in the same manner as an engineer takes up his Trautwine or Rankine if he wants to get facts relating to an engineering problem; and in the Bible we find that the Sunday question is dealt with in no uncertain way. The institution of the Sabbath seems to date back to the earliest times, as we find that in the time of Moses the commandment with respect to it begins with "Remember the Sabbath," clearly indicating that at that time it was already observed, and there is no doubt that the day was set apart by the wisdom of God, for the benefit of mankind, both physical and spiritual, but especially with regard to his spiritual nature, as the Sabbath day commandment is one of the four dealing with man's relation to God. Christ's words that the Sabbath was made for man and not man for the Sabbath endorse this view, and his whole teaching in connection with the Sabbath shows clearly that the day was for man's blessing and not his hindrance.

About 20 years ago I left the United States and went to New Zealand, and the only experience I had at the time with regard to Sunday work in mining was that it was the proper thing; and when, after I had been in New Zealand for some years in charge of mines, the question was brought up by the Government, with a view to passing a law to stop Sunday work in the mines and mills; I naturally joined with my fellow managers in protesting against the proposed action. However, the law was passed, and I can now honestly say that I look back with shame at my foolishness in standing against that which God had ordained (see Acts V, 29) and I think it safe to say that, after having experienced the Sunday closing of the mines and mills in New Zealand, there is not a manager of a single reputable company there who would like to go back to the old conditions.

The cry of the mine-owner against Sunday closing is that he is going to lose his profit, and the cry of the worker is that he is going to lose his wages. Of course, this looks plain enough, but it is well to remember that human calculations are not of much importance in the sight of God, and Sunday profits and wages are apt to turn to ashes. Since returning to the United States I have seen and experienced a great deal of Sunday work and I can truthfully say that I abhor it. To work day after day without a break, Sunday, Good Friday, Easter, and even Christmas, has a most deadening effect, and there is no wonder that when a man has had about six months of it, he calls for his time, and takes the nearest route to a 'wet' city, and has a 'bust.'

I doubt whether it pays from a financial standpoint. A man naturally goes to his work with more zest on Monday if he has had a change from toil on Sunday, and he takes more interest in it—he is better off physically, and there is no question about the spiritual gain, unless he is a man whose bringing up has given him no better way of spending his leisure than to loll about and engage in idle conversation. There are better ways to spend Sunday than this.

Under the New Zealand law, permits are granted by the Inspector of Mines for working men on Sunday at repairs in the mills, and also for pumping, etc., in the mines. When a mill is closed down and free from noise, a repair-man can do about twice the amount of work and do it better than when he has to do it while the machinery is in motion.

Upon whom should the blame and responsibility for the existing conditions be placed? The men claim that they have to work on Sunday or lose their job; the management says the directors require Sunday work, and that the men also demand it; the directors wash their hands of the whole matter and say that they leave these details to the manager, and the shareholders clamor for dividends and ask no questions about the necessity or advisability of Sunday work.

Clearly the directors and shareholders are the responsible parties: they can say 'this' or 'that,' and have the authority to enforce their requirements. It is still the old story; money first and God second place. Away back at the dawn of the human race, wicked Cain evasively asked "Am I my brother's keeper?" and this question has been ringing through the ages ever since, and is answered by faithful Paul in his well known statement which contains the whole essence of brotherly love: "Wherefore, if meat make my brother to offend, I will eat no flesh while the world standeth, lest I make my brother to offend."

F. C. Brown.

Boise, Idaho, May 24.

Chinese Mining Regulations

The Editor:

Sir—Replying to your kind invitation of March 21 to comment on your editorial on this subject in your issue of March 18, I take pleasure in making the following remarks.

Were Mr. Lindsey entirely unknown and unheard of to me I should be inclined to welcome any change he might make, preferring unknown evils to those already experienced, but with his enviable reputation and the tribute you pay to those particular qualities of his which are sure to be called on so extensively in the task before him, I welcome most heartily the news that he is to give us a new set of mining regulations, confident that if not too much hampered there will be not only no harm in them but salvation for the mining industry of China.

It is unnecessary to discuss on this occasion the local need of a new mining law in China, and I will pass it on with a word or two. To my mind too much emphasis is laid, even by many of the younger engineers, on the need of something very special in the way of a mining law in order to conform with the multitudinous traditions and customs of China. It may be safely said that the more heed paid to these ignorant superstitions and inefficient customs, by just so much greater extent will

the good effects of any law be vitiated. China is in a great transitional stage, even a rapid one; let us have a No. 1 mining law and grow up to it instead of settling down to a makeshift. Of almost equal importance with a good law is its honest and intelligent administration; the law-makers should bear this strongly in mind. Make a civil service examination necessary and offer an adequate salary and then make it possible to put the fear of God into any official attempting 'squeeze.'

The two salient objections to the present regulations are the difficulties and restrictions put upon the prospecting and opening of mining property, and, the restrictions put upon foreign capital. These must be remedied before mining can flourish in China in the manner that it should.

Regarding foreign capital, I consider it of the first importance and am decidedly in favor of attracting it to China by means of favorable legislation. In the first place, it will develop the mineral resources of the country at once instead of fifty or a hundred years from now, and will bring with it all the benefits attendant on the economic production of raw material. Next, it will educate the people of China in all phases of the mining industry. It will educate the miner, the superintendent, the manager, the director, the president, and the capitalist. It will tend to create an efficient mine administration; in short, it will serve as a great school to train the actors for the great drama of economic mining in China; the stage is already set.

The question now arises, until a greater number of Chinese are educated up to the modern mining industrial standard, should there not be some kind of limitation put upon the number of foreign enterprises, lest before the Chinese are able to stand upon their own feet and play the game, practically all of the best properties in the country would be in the hands of foreigners? Just how this limitation should be applied or whether there should be any limitation is a question that should be decided only after the sifting of many opinions and the most careful study, but it has occurred to me that a geographical limitation might serve the purpose from the Chinese view-point and at the same time need not in any way discourage foreign capital. Suppose, for instance, within a single district or Fu (the average Fu has an area of about 2500 square miles), say, four properties were opened to foreign capital. Their engineers are allowed to prospect, examine, and choose without restriction, but once the limited number is taken up or purchased, then that particular Fu would be closed to further foreign capital. The details of such an arrangement, I believe, could be satisfactorily worked out. It seems to me that the effect of such an arrangement would be to stimulate the entrance of foreign capital rather than otherwise. A limited edition is always more coveted than an unlimited one. This would give the Chinese about the right handicap and once they learn how, the limitation could be removed, as they should then be able to hold their own with all comers.

Such foreign capital as is allowed to enter should be given full freedom of control, but under the Chinese law. There must be no hint of extra-territoriality.

Hongkong, May 6.

What Mining Men Read

The Editor:

Sir—In 1910, when the Porcupine gold district was 30 miles from a railroad or any other kind of a road, the engineers and mining men there liked to 'stop-over' for a meal or a smoke at the Porcupine-Vipond mine. One reason was that Bert Poirier, the manager, extended the hospitality of his comfortable cabin without making the visitor feel uneasy. The other reason was that on the table were periodicals from the outside world. In spite of the busy times characteristic of a new district, the better-class weeklies—both technical and general—were read with an avidity that had to be seen to be appreciated. This is not unusual. Men who have journeyed to the ends of the earth comment upon the eagerness with which people cut-off from the world watch for the periodicals to arrive. A significant point is that a man on the fringe of civilization or in a foreign country will choose the really well-written papers instead of trash. A residence in a strange land gives the sojourner a new point of view: he looks at things in a detached way, and learns to appreciate the best in his native country. The New Yorker in Chile or the San Franciscan in China does not want to receive the newspaper that features "Woman Leaps from Ferry" or "Heart Balm Awarded Soul-seeker's Affinity," but he wants papers written by intelligent journalists. If more of us could spend a year at a lonely mine in the Andes or Siberia, I think that our literary taste would be raised considerably.

A recent article in the Technology Monthly of Harvard University deplored the neglect of real literature by the engineer. The criticism was made that the technical student's reading is too apt to consist only in 'skimming through' the engineering periodicals. This may be true of the student, but it does not apply to the same man five years later, when he has got over the frivolous methods of the modern undergraduate. Particularly it does not relate to the graduate who has to do with mines. An experience in the mining industry is likely to mean more or less traveling, and an acquaintance with danger, both of which make for seriousness and breadth of view. J. Parke Channing remarked recently concerning a mine in the desert region of the Southwest, that he noticed many of the staff took the Sunday edition of the *New York Times*, and a surprisingly large number of that same excellent paper is sold every Thursday at the news-stands here in San Francisco. The proportion of Americans who are learning to distinguish a real newspaper from a 'sob sheet' is on the increase. The market for good writing is growing.

Berkeley, June 1.

Notes From Lake Superior

By P. B. McDonald

An ore-carrying steamer broke in two and sank in Lake Superior four miles off Keweenaw point on May 9, most of the crew being lost. This steamer, the *S. R. Kirby*, was taking iron ore from Duluth to the lower lakes, and was probably overloaded. It is a temptation to overload an ore-steamer, because a full load of the heavy iron ore scarcely more than covers the bottom of the boat. On the same date a steamer left Houghton carrying 3500 tons of copper valued at $2,100,000, the most valuable cargo ever sent down the lakes.

A horizontal diamond-drill hole, 1575 ft. long, near Juneau, Alaska, has attracted attention in the West on account of its great length for a flat hole and the practical difficulties of handling such a long line of rods. As pointed out by George Newett of Ishpeming, 1600 ft. for a diamond-drill hole is nothing remarkable in Michigan, where holes of 3000 ft. depth are common. But it should be remembered that a horizontal diamond-drill hole is much more difficult to drill than a vertical hole, by reason of gravity, freezing, and other troubles.

The recovery of fine flaky native copper is engaging the attention of Michigan metallurgists. This applies not only in the new White Pine district, where 67% recovery, equal to 25 lb. per ton, is being made by the White Pine Copper Co., but also at the Winona mine where a leaching process is being tried, and at Keweenaw Copper Co., where the Ash-bed lode contains flaky copper in spongy rock. Tailing carrying up to 12 lb. of copper per ton is being stored for future treatment, while experiments with flotation and leaching processes continue, as a sequel to the work of C. H. Benedict.

A dividend of $1 per share is mentioned for Isle Royale Copper Co. This would be the second dividend paid, the first having been in 1913, although mining was started on Isle Royale land in 1853, the present company having been organized in 1899. A striking contrast is the record of the Quincy mine, which is within sight of the Isle Royale. The Quincy paid its first dividend in 1862, which was 54 years ago, and except for 1866 and 1867, has paid dividends every year since. It is still a remarkably profitable mine, with a long future ahead.

The Ahmeek is the best mine of the dozen subsidiaries of the Calumet & Hecla. Last year it sold 21,800,492 lb. of copper at 18.28c. per lb., the cost of production being 7.96c. Four dividends, totaling $1,650,000, were distributed during the year. All operating expenses were $1,734,919, a sum only slightly larger than the dividends paid. The new stamps added to the mill, raising the total to eight, will make the third largest mill in the Copper Country, with a capacity of over 5000 tons per day.

Lake Superior people are trying a little speculation in a Wisconsin lead and zinc venture. Shares of the Platteville Consolidated Lead & Zinc Co. have been offered in the Michigan mining towns, although the company is directed from Chicago. In the past, Lake Superior men have lost money in Wisconsin zinc mines, because they have assumed that the irregular little bodies of zinc could be mined according to the big-scale methods applicable to copper and iron.

Calumet & Hecla produced 72,613,320 lb. of copper in 1915, of which 51,738,588 lb. came from the conglomerate lode, and 1,582,802 lb. from the tailing in Torch Lake. The yield of copper per ton of ore has declined steadily; in 1873 it was nearly 5%, in 1889 about 3%, in 1907 about 2%, in 1915 it was 22.28 lb. or slightly above 1%. Regarding the acquisition of the stock of the Tamarack mine, as to which some difference of opinion has existed, a large majority of the Tamarack shareholders accepted the price of $59 per share offered by the Calumet & Hecla. W. E. Parnall and James MacNaughton differed materially in their appraisals of the Tamarack mine, whereupon the directors of the company stated that they "naturally do not undertake to decide which of two competent experts is right in so technical a matter." As to the C. & H. reclamation-plant for treating old tailing, the production, with three-quarters of the plant in operation, is at the rate of 5,000,000 lb. per year, at a cost, excluding smelting and selling, of about 4c. per pound. A 20-in. suction-dredge of a capacity of 10,000 tons per day, electrically driven and capable of digging 100 ft. below the water-line, operates in Torch Lake. The tailing is pumped to the classifying-house, through a pipe-line on pontoons. In the re-crushing house are 64 Hardinge mills.

The management of the Copper Range Consolidated believes in producing a maximum amount of copper while the price for the metal is high, rather than send a maximum amount of low-grade ore to the mill in order to extract copper from rock that would not be 'ore' in normal times. For this purpose the rock is sorted carefully and only the higher-grade ore sent to the mill. The average content of ore milled in 1915 was 32 lb. of copper per ton, which is a decided increase over the figures of 23 and 25 lb. per ton in the two years previous. The production of the Copper Range Co. last year was 37,035,642 lb. of copper, the largest in its history, the profit of $3,459,236 being particularly gratifying. The cost of production was only 8.06c. per pound, compared with a previous cost of 10 and 11 cents. A significant note is the statement by the president, William A. Paine, that the company's new selling department, opened a year ago in New York, has effected a considerable saving in commissions. The general manager, F. W. Denton, states that in 1915, 220,920 cu. yd. of stamp-sand was run into the Champion mine for filling stopes, and 54,240 cu. yd. was filled at the Baltic mine. This sand is piped to the stopes, where the miners require additional waste-rock to enable them to reach the back, and is cheaper than the old method of breaking wall-rock for the same purpose.

Surficial Indications of Copper—III

The Chemistry of the Oxidized Zone

By Frank H. Probert

AN outcrop is not necessarily ore-bearing or characterized by gossan; rock alteration may be the sole indicator of the chemical processes that have acted in conjunction with dynamic forces to concentrate metallic minerals to form ore.

In the wonderful laboratory of the earth's crust, the same laws govern the reactions as those we were taught in our first lessons in chemistry. Acids combine with bases to form salts; molecular re-arrangement produces new compounds; chemical affinity rules in an interchange of atoms; the laws of valency are never violated. It is the same old story that, under favorable conditions, $H_2 + O = H_2O$.

This is true near the surface of the earth, or in the zone of weathering, but as we go deeper our knowledge of chemistry must be more advanced. Other factors enter into the reactions; high temperature, great pressure, mass reaction, the laws of solution, the laws of colloids, and the like, upset chemical equilibrium and bring about conditions which, try as we will, we cannot duplicate in the laboratory. We can theorize, postulate, and argue, but we cannot conclusively prove. The physical chemistry of mass reactions is but imperfectly understood. We can never determine blast-furnace practice by test-tube experiment.

Plant life accomplishes a chemical function of no little importance. Decaying vegetation furnishes acids to attack the surface rocks and minerals. J. J. Beeson, in explaining the formation of surface carbonate ores at Bingham, says[1] that "prior to steam-shovel operations, the surface of Bingham was heavily brush covered. This decayed during summer months producing humic acids and carbon dioxide, part of which remained in the soil to be later dissolved by atmospheric water. As the waters advanced down the hillside, the CO_2 and alkaline carbonate content was increased, so that on the middle slopes, copper carbonates were precipitated by reaction with sulphate waters in the rock." Meteoric waters, with the soluble salts of the surface, are the active agents of all changes brought about in the zone of oxidation.

Of the water that falls on the surface, only a small part sinks into the rocks. The water in the belt of weathering is that held by imbibition, or adhesion, between the water and mineral particles. Locally, and for a time, the belt of weathering may be completely saturated. The activity of the water is dependent on the compounds present, and the temperature. The variability of pressure at this high horizon is negligible.

Both water and gaseous solutions are active. The chemical changes of the rock-minerals assist in the alteration of the contained metals. When the rocks are not saturated with water, gases are held in the pores and fractures so as to act as important chemical reagents. Much oxygen is carried down in the vadose circulation. Rain will absorb atmospheric gases; it will also dissolve haloid salts from passing over the surface, particularly in desert regions. Nitrates similarly may be taken into solution. These waters will attack and dissolve the alkaline earths and metallic salts, the solutions causing a series of chemical reactions of extraordinary complexity. The temperature in the belt of weathering is subject to changes due to climatic conditions. The average annual temperature near the Arctic circle is about –15° C. At the tropics it is 27° C. Since solutions are much more active at higher temperatures, alteration is much more apparent in the lower latitudes.

The important reactions are those of oxidation, carbonatization, hydration, solution, and deposition. The oxygen of the air may act at the surface directly as a gas, but to a far greater degree through solutions.

The break-down of organic matter results in the liberation of carbonic acid gas. Carbonatization is chiefly accomplished through the substitution of carbonic for silicic acid. Carbonated waters will attack the feldspars, forming alkaline carbonates, and liberating free silica, part of which may be taken into solution as colloidal silica and part separate out as quartz. It has been ascertained that where vegetation is abundant, the amount of dissolved silica in underground water is much greater than in non-forested regions.

Hydration and dehydration are dependent on humidity or aridity. The combined work of carbonatization and hydration make solution the more active. No substance is wholly insoluble in water, even at normal temperature and pressure. Under conditions of deep water-circulation, even refractory silicates are readily soluble, as instanced by the replacement of the pebbles of the Calumet & Hecla conglomerate by copper.

A unit of solution simultaneously saturated with each of several compounds contains a greater total of solids than a unit of solution saturated with fewer of these compounds, but less of any individual salt than it would were it saturated with that salt alone. The influence of

[1]Trans. A. I. M. E., New York meeting, 1916.

one compound on the solubility of another plays an important part in the reactions of the oxidized zone.

The volume of a solution is less than the volume of the solvent, plus that of the solute. It is clear, therefore, that pressure increases solubility, for solution tends to bring the molecules closer together. When soft glass (similar to many natural silicates) is dissolved in water at 210° C., the volume of the solution is 20 to 30% less than the total volume of water and glass.

Solution is the great factor in the belt of weathering; it is augmented by increase of temperature. The relative solubility of the salts formed by oxidation determines, in a measure, the sequence below, for substances dissolved in the greatest quantity are deposited in the greatest quantity. Where the evaporative factor is high, surface concentration may result.

As a sweeping generalization, I may assert that nearly all the primary ores of copper deposits are sulphides and that whatever the form, genesis, or character of the deposit may be, the oxidation, if it takes place at all, will be practically the same. In the first two of this series of articles, I have analyzed the physical conditions that accentuate secondary concentration in the oxidized zone, or in the deeper zone of sulphide enrichment. The porosity of the mass, the opportunity for the free passage of meteoric waters, is the prime essential. Quoting Ransome[2] on Bisbee: "The most marked physical effect of oxidation has been the great increase in the porosity of the masses acted upon. This has greatly facilitated the migration and concentration of the desulphurized ores and their segregation in workable masses from the bulk of the limonitic and clayey ledge matter. The oxidized material is more porous, softer, and more plastic, hence it weakens the rocky structure in which it occurs, causing a settling of the mass. This enhances solution and oxidation is made even more rapid. This, in turn, assists erosion." The sequence or zonal arrangement we have established, or perhaps accepted, in its relationship to the surface and ground-water level. We have seen how these zones are constantly descending as erosion proceeds. The solutions are finding new material at the bottom of the belt on which to work, therefore, as denudation goes on there is ever a belt contributing material to the zone of cementation below.

Certain minerals have their critical level, which they cannot leave without decomposition, while others have such a large interval of existence that they may be called persistent.

Copper is a peculiarly soluble metal in all its compounds. The sulphides are exceptionally vulnerable to descending oxidizing waters.

Ore minerals are variously altered by atmospheric oxygen, both in degree and rapidity. Stephen H. Emmens says,[3] "The important sulphides are attacked in the following order: marcasite, pyrite, pyrrhotite, chalcopyrite, bornite, millerite, chalcocite, galena, blende." Pyrite and marcasite are the same chemical compounds having different molecular structure. They do not oxidize or go into solution at the same rate. Pyrite is the more stable.

The presence of free air seems to be essential for the solution of some sulphides, and as not all portions of oxidizing deposits are equally accessible to atmospheric oxygen, residuary sulphides may be left in the upper parts of copper deposits. Chalcocite is stable in the absence of air, although, in the presence of highly oxygenated waters, it is more readily attacked than pyrite.

Oxidation and solution go hand in hand, but reduction and precipitation are not so closely related. Copper is more soluble than gold, and even where conditions are most favorable for the solution of the gold, it is precipitated as soon as the ferric liquors of the surface are reduced to the ferrous state. Residual gold is often left in the outcrop, hence there is a segregation—a relative enrichment near the surface. This explains the transition of the Mount Morgan mine of Australia from one of gold to a steady producer of the red metal. At the Highland Boy, of Bingham, and at the United Verde, of Jerome, there is a concentration of gold at the surface. H. H. Knox has described,[4] the pyritic deposits of Koninkhoff, in Russia, where precious-metal concentration is particularly well exemplified. Silver is freely soluble in ferric sulphate, but if chlorides are present it is at once precipitated as cerargyrite, and with the reduction of ferric solutions, the native metal will drop out. The Old Dominion mine, of Globe, was worked for many years as a silver mine, and it is not at all unlikely that the present silver lodes of Butte, on which the Alice, Moulton, and Silversmith mines are located, will be worked eventually for copper.

It is perhaps advisable, at this stage of the discussion, to consider the reactions that take place. I have prepared a series of chemical equations, suggesting the sequence of change. It must be understood, however, that such simple formulas cannot express the actual complexity of reaction.

Copper sulphides, in primary ore, are invariably associated with iron sulphides. Recent researches at Butte and elsewhere tend toward the recognition of primary chalcocite at great depths, but, in nearly all deposits, copper and iron sulphide occur together. The oxidation of these sulphides produces the potent liquors.

The mineral waters in the zone of oxidation are acid and metallic sulphate solutions. They react not only on the vein-filling, but on the wall-rocks. The nature of the wall-rocks often plays an important part, particularly if a wall-rock contains much lime. The solutions readily give up their metallic content when in the sulphide zone. The reactions and products will vary with the material acted upon, and an understanding of this fact will guide the geologist in anticipating the future. We must always bear in mind what the physical forces have done in the district under investigation. Broadly speaking, the drier the climate and the less precipitous the surface of

[2]Prof. Paper U. S. G. S. No. 21. Page 159.

[3]'Chemistry of Gossan,' E. & M. J., 1892. Page 582.

[4]Trans. I. M. & M., 1909. Page 273.

the land, the more pronounced will be the surface evidence of mineralization, and, in all probability, if long continued erosion is established, the chances are greater that enriched ore is now being oxidized.

Primary ore near the surface at one time or another will run the whole gamut of the list of equations given. The sequence is the same no matter what type of deposit we study, but the rate of change varies with the physical condition of the deposit.

Cupriferous pyrite, a physical mixture of iron and copper sulphides, may be accepted as the general condition of primary ores of copper. The association of these two sulphides seems to increase the rate of oxidation. Gottschalk and Buehler state[5] that the oxidation of certain natural sulphides is greatly increased by the presence of either marcasite or pyrite, and deduce from elaborate experiments the following explanation:

1. That while there is, in mixtures of two sulphides, a large increase in the solution of the one, there is also a protective action exerted on the other.

2. That there is a difference of potential between the different sulphides which can be arranged in a series similar to the electro-chemical series shown by the metals.

3. That this fact may be of the greatest importance in the process of natural oxidation.

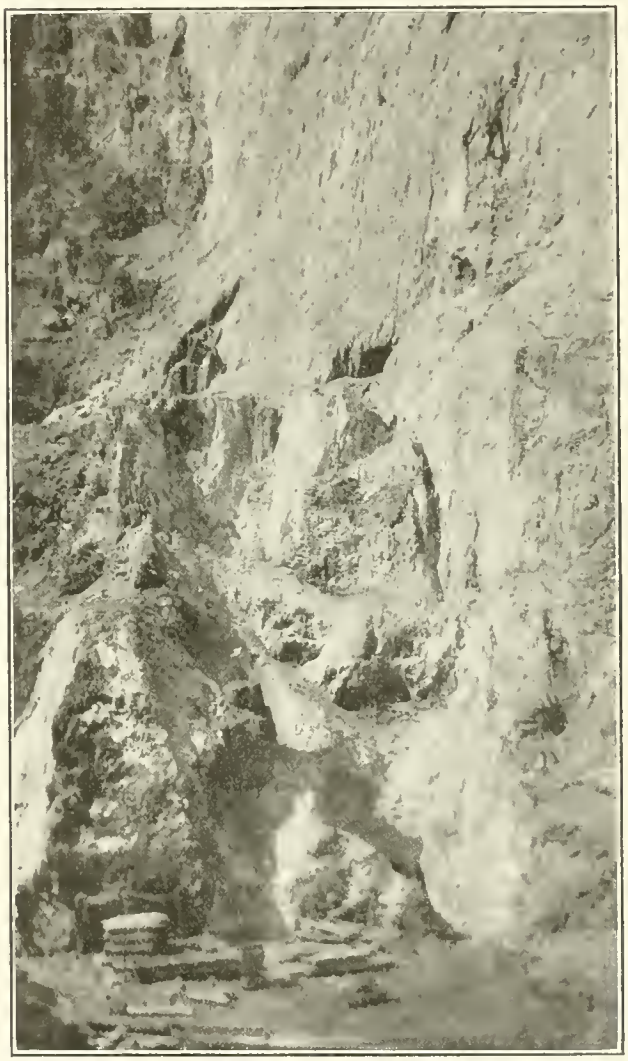
The oxidation of the mixed sulphides may be partial or complete, according to the time they have been subjected to the process. The first step in the break-down is the formation of ferric, ferrous, and basic sulphates with free acid, as expressed in equations No. 1 and 5. The ferric-hydrate may, by hydration, separate out as limonite. Under changed climatic conditions, this may be dehydrated again, producing the hematitic outcrops so common in desert regions. In wet mines, where pyritic ore is subject to rapid oxidation, an orange-colored gelatinous mud will accumulate on the floor and sides of old workings. This is a gel form of limonite, and with it minute black scales of specularite are often found. Limonite may occur as pseudomorphous replacements of pyrite cubes, or staining the silicious skeleton of pyritic casts.

The deep oxidized copper ores of Bisbee occur in limestone abundantly altered to limonite. There is a slow replacement of the limestone blocks by mineral waters. Rhomboidal cleavage has developed in the lime-rock and the waters, filtering through the bedding and fracture-planes, deposit at first a thin film of yellow limonite; the angular corners of the blocks are worn away, the blocks take an ovate form, the limestone is slowly replaced in concentric layers until finally the whole is a mass of hydrated iron oxide. Cupriferous waters produce the same effect and fine malachite specimens often surround residual masses of limonite.

Carbonated waters may cause siderite to form, but this is not common in the outcrops of copper deposits.

Hematite generally attracts the eye on account of its striking color. It is plentifully developed in the arid regions. The dehydration of limonite causes a shrinkage of volume of 27%, hence the cavernous 'burnt' nature of so many iron outcrops on the desert. This increased porosity, due to chemical change, is a great factor in promoting vigorous circulation. If the country or vein is faulted after mineralization and oxidation, micaceous hematite may develop by attrition. At the Old Dominion mine, in Arizona, the hematite of the gossan is quite greasy.

The influence of the wall-rocks on the character and distribution of the ore in the Old Dominion mine is strikingly shown on the different levels. Rich carbonate and iron ores are found where the fault brings diabase and limestone into juxtaposition, or where fault-blocks of limestone have been caught in the vein-filling or floated in the cooling diabase and replaced. Cuprite and native copper are common in the quartzite, while the sulphides are almost wholly developed where both walls of the vein are in diabase. The presence of these rich products of meteoric waters at the higher horizons coupled with the slight development of chalcocite on the 800-ft. level convinced me, during my examination of the property in 1901, that the original pyrite had been suf-



UNITED VERDE OUTCROP, JEROME, ARIZONA.

[5] *Economic Geology*, Vol. 7, page 15.

ficiently cupriferous to form ore by processes of concentration.

Hematite is the final product of oxidized pyrite. In the arid regions, where ground water lies deep and the precipitation is slight, the solutions percolating through the oxidized zone are likely to be of a concentrated character, and if pyrite, marcasite, or chalcopyrite is abundant, and if the mass is porous, the chemical changes involved in oxidation may be so energetic as to develop considerable heat. This may explain the formation of specularite or micaceous hematite instead of limonite in gossans. Gagel has shown that the presence of salts in solution lowers the water-tension and permits of the formation of hematite at low temperatures. It is frequently quite silicious owing to the alteration of other gangue-matter, in which case it will weather out in bold relief.

The vein mines of the Globe district are remarkable because of the great development and depth of the hematite in the oxidized zone. It was the sole indicator, and that in one short exposure, on which I pinned my recommendations for the development of the Superior & Boston property. At the Black Oxide mine, practically the whole vein-filling, which occupied a fault in diabase, is of this micaceous variety of hematite. It averages about eight feet wide and shows no change in its general character at a depth of 600 ft. below the surface, although a winze sunk from the lowest level opened a lens of rich carbonates in the hematite matrix. An incomplete analysis of the ore showed

	%
Copper	6.20
Silica	18.45
Alumina	5.80
Iron (metallic)	43.90

Under the 'blow-out' of the Black Hawk, mixed carbonate and glance ore was mined to a depth of 500 ft. where a leached crushed zone, containing hematite and occasional kidneys of ore, gradually merged into the cupriferous belt below.

At the Swansea and Planet mines, in Yuma county, Arizona, hematite is even more plentifully developed, but the district does not promise to become a large or steady producer of copper. It presents the typical desert topography. The hills have fairly regular slopes, although recent ravines have been incised by torrential rains. The pre-Quaternary contour was vastly different from the present detrital surface. The geologic sequence is quite complex. Resting on a basal series of gneissic granite, metamorphosed limestones and argillites are seen. These were intruded by a basic rock subsequently changed to amphibolite and heavily pyritized with barren sulphides. All these rocks were cut later by a series of volcanics. The ore deposits of Swansea and Planet are of the 'replacement' type. They are essentially iron-copper deposits in the sediments and closely associated amphibolites, and are apparently confined to this series. They are limited below by the gneisses and above by the conglomerate. Oxidation is advanced to a degree such that the original nature of the deposit is lost, but I am of the opinion that the primary ores consisted of specularite, low-grade cupriferous pyrite with accompanying quartz, calcite, and siderite as vein materials. Specularite or micaceous hematite, the predominant mineral, is, I think, in part primary and partly secondary. The origin of such enormous masses of micaceous hematite has long been a subject of interest to the mining geologist. Abundant evidence is now available to prove that it is frequently a direct product of pyrite, whether cupriferous or barren. Cupriferous pyrite is, as I have said before, an intimate physical admixture of minute crystals of chalcopyrite in the interstitial spaces of normal iron pyrite. This sulphide will oxidize first, leaving brownish rusty pyrite grains as loosely coherent masses. The presence of chalcanthite in the gossan, the absence of carbonates or silicates, and the low-grade copper tenor of nuclear masses of pyrite in the secondary hematite, convinced me that the chances for valuable ore deposits at Swansea are remote.

The copper deposits of north-western Arizona were studied hurriedly by Howland Bancroft. In reply to enquiry concerning the great quantity of hematite there found, he writes me from Chile that "In the central-western part of Arizona there is more specularite in a small area than anywhere else I can now recall. I am convinced that the specularite is the result of primary deposition from solutions, which, I think, were the result of dehydration by dynamo-metamorphism. The hematite which is common in the same district, is, I believe, entirely secondary, and may have originated from the breaking down of the so-called primary specularite, or from the oxidation of pyrite. I am inclined to the view that it is the result of the incomplete breaking-down of specularite. I am aware that specularite and hematite presumably have the same chemical formula. However, I think that more research would disclose other differences between the two minerals than the physical appearance. Red or black hematite, found in igneous regions unassociated with specularite is almost invariably an indicator of pyritic masses, and I believe this view is substantially in accord with the views of many others."

Hematite is also found in the capping of contact metamorphic deposits, but here it is an oxidation product not alone of the chalcopyrite or associated iron sulphide, but of the lime-iron garnets and the magnetite.

Magnetite is seldom an oxidation product, but is a common constituent of igneous rocks and magmatic segregations. It is generally primary. L. C. Graton, in speaking of Shasta county, California, says:[6] "The extent to which magnetite may form in the outcrop of a sulphide orebody is a matter of considerable importance in connection with the prospecting of gossans. It is sometimes found at the surface in considerable quantities as a result of certain peculiar climatic conditions. Outcrops of magnetite have been regarded as the cappings of sulphide ores below. At most places, it has been found that massive magnetite is of primary origin and is persistent in depth. If rock making minerals or the

[6]Bull. U. S. G. S., No. 430. Page 106.

heavy silicates such as garnet, actinolite, etc., are intergrown with masses of magnetite, it may safely be regarded as a primary deposit, and one cannot fail in their deductions concerning it."

Before leaving the iron oxides, I must comment on the concentration of manganese oxides in the upper zone of oxidation. In the old Detroit and Manganese Blue mines at Morenci, Arizona, now exhausted, there was a series of replacement orebodies in different limestone strata, rich in oxides of manganese and copper carbonates. Earthy manganese oxide occurs with limonite in the replaced limestone orebodies at Bisbee. It is not an uncommon associate and may be greatly concentrated in the upper oxidized portion of an orebody.

The series of equations shows that acid and metallic sulphates are the main products of the first break-down of primary sulphides. The sulphates are readily soluble and are seldom precipitated to form workable orebodies. Exceptions are rare. The bluestone of the Yerington deposits is evidently a direct oxidation product of the chalcopyrite (Equation No. 8). At the Central mine of the Detroit Copper Company, Morenci, chalcanthite forms as an oxidation product of chalcocite. It is found above the secondary sulphides, never below.

At the Planet mine, Bouse, it occurs as veinlets and efflorescences in the oxidized material, but not in economic quantity. In old and abandoned workings, it will sweat out of the wall-rock and often makes a showing altogether disproportionate to the value of the rock from which it comes.

Brochantite, the basic sulphate of copper, is more stable than the normal salt, hence it is of much more frequent occurrence in the upper zones of copper deposits, particularly in hot climates of little rainfall. It was recognized by Waldemar Lindgren at Morenci, and is not infrequently mistaken for malachite. At the Chuquicamata mine, in Chile, practically all the ore is brochantite. Lindgren ascribes its formation to the oxidation of chalcocite in the highly altered porphyries.

Pisanite, the mixed sulphate of iron and copper, is found in stalactitic form, especially in old workings through lean pyritic ore. All these sulphates are of a distinctly blue color. They cannot be mistaken for the yellowish melanterite. Where melanterite forms as incrustal masses, the chances for valuable copper deposits are slim.

The carbonates of copper, malachite and azurite, are perhaps the most common minerals of the oxidized zone; certainly they are the most attractive. Malachite occurs in many beautiful forms, particularly in association with limestone rocks. It is always an oxidation product of sulphide ore; it is never primary, and has been pre-eminently the indicator that has encouraged the prospector to dig.

Malachite, as it occurs in the limestones of Bisbee and in contact metamorphic deposits, is formed by direct precipitation from sulphate waters. At the Apache mine, in New Mexico, it is found replacing the angular edges of calcite crystals. Azurite is closely related to malachite and the two occur together. I need not dwell on the significance of the carbonates when found in a region of limestone invaded by igneous rocks, but its presence in schistose and porphyritic rocks of the disseminated copper type must be carefully studied. Under such conditions it is frequently an oxidation product of secondary sulphides and the quantity of it may be the measure of the degree to which the chalcocite ore has been oxidized and eroded. In the first case the carbonates have formed through the agency of sulphatized waters, in the latter it is probably carbonatization, for there is insufficient pyrite to form strongly acid solutions, so that the copper, instead of migrating downward, remains at or near the surface, brilliantly stain-

CHEMICAL EQUATIONS EXPLAINING THE LEACHING AND ENRICHMENT OF COPPER ORES.

ing the rocks with chrysocolla or malachite. Ransome says of the Miami district: "The largest orebodies are not found under those surface rocks that are most vividly colored by copper compounds or iron oxide." With this statement I am inclined to agree, as it is supported by observations in many other localities.

At Rossland, B. C., C. W. Drysdale reports malachite as coatings on cleavage-planes and as staining the clayey gouge. He also says: "Malachite may be seen in the process of deposition wherever downward seeping surface waters trickle into the mine workings."[3]

At Rossland and Kootenai the outcrop of the veins is seldom visible on account of glacial soil. Moreover, the oxidized capping and probably the enriched sulphide zone was removed by the Pleistocene ice-sheet.

At the Cactus mine, a few miles north-west of Globe, seams and slabs of copper carbonate form a network in the highly altered sericitized schist. Churn-drill operations failed to disclose any area of enrichment, lean sulphides being found a short distance below the surface. This condition may be caused by an early arrest of the locally concentrated copper waters in the fracture-planes, probably due to carbonated surface-waters. The minerals are definitely crystalline and do not occur in the rock-mass, but as coatings along lines of weakness. I found the same condition at the Piedras Verdes mine, near Alamos, in Sonora. Had the minerals formed by carbonatization of enriched sulphides, a more general distribution throughout the rock-mass would be expected.

The silicates of copper are all due to meteoric waters and form a large part of the oxidized products in the upper zone. Chrysocolla is the one best known. It occurs in both igneous and aqueous rocks, although more frequently in rocks of acid character. Surface-waters containing carbonic-acid gas from the air, decaying vegetation or from calcareous rocks will react with the alkaline silicates, particularly the feldspars, liberating silicic acid from which secondary silica may crystallize out, or combining with metallic-sulphate waters, the several silicates may be precipitated. The same remarks apply to the silicates as to the carbonates regarding enrichment at depth.

Colloidal silicates are always forming in the belt of weathering owing to the reaction of carbonated waters on gangue or rock-silicates. While studying the Butte district, I noticed an accumulation of a gelatinous colorless slime on some joint-planes of the pyritized granite, which, on analysis, was found to be colloidal silica. On the 200-ft. level of the Ray Central mine near the top of the disseminated ore, one of the drifts was coated with a jelly of the most beautiful shades of blue and green. Terraces had formed on the floor of the drift. It was a gorgeous display of soft colors. Chemical analysis of the solid substance showed

	%

It was a hydrous copper silicate closely related to chrysocolla and was forming from oxidizing chalcocite.

The study of mine-waters or surficial waters running over rocks supposedly mineralized is instructive. Many shallow deposits of copper conglomerates are known in Arizona, caused by the deposition of silicates as a cement in gravel and sand. Copper salts are often taken up by clays by absorption. I have seen many interesting samples of this condition, but none of economic value.

To continue our study of the zone of oxidation, it is necessary to accept the reactions, simple and complex, brought about by the changed conditions at ground-water level. The migration of the metal downward is here stopped, the environment changes from that of oxidation to that of reduction and precipitation. The metallic burden is deposited, and enrichment of primary ores results. Chalcocite, covellite, and kindred sulphides are formed as shown by equation No. 10. We have seen that in the downward migration of the metallic-sulphate waters, part of the copper will, under given conditions, separate out as carbonate, silicate, or sulphate. As it approaches the ground-water level, the environment changes, the oxygen is used up, air is excluded, and further reactions take place in a reducing atmosphere. Copper is precipitated as chalcocite, covellite, bornite, chalcopyrite, enargite, etc. The precipitation is often of the nature of metasomatic replacement, and pseudomorphic structure may result. As the solutions descend they lose acidity, copper sulphide is precipitated at the expense of iron sulphide. A decrease in acidity, a decrease in copper, and an increase in iron in solution bring about a state of equilibrium that is increasingly favorable to the precipitation of double sulphides.

At and near the ground-water level many complex reactions, as yet imperfectly understood, take place. The oxygenated sulphate waters in contact with enriched sulphides may bring about reverse chemical changes, so that chalcopyrite is rejuvenated. Beeson, as a result of preliminary experiments in the laboratory of physical chemistry at Stanford University, tells me that "solutions rich in iron or those containing a proper catalizer in the presence of certain iron minerals, under slightly acid, neutral, or alkaline conditions, reacting on chalcocite or bornite, will readily form chalcopyrite. Great pressure is not necessary for reverse reactions. A small quantity of sulphuretted hydrogen will act as a catalytic agent. Chalcocite in contact with hematite in the presence of sulphuretted hydrogen soon becomes coated with chalcopyrite."

The presence of lime carbonate in ore or wall-rock will check the downward migration of metallic sulphates. Hence chalcocite is seldom found in limestone rocks. Free acid in the solutions may, however, convert part of the carbonate to sulphate—an insoluble substance—and so admit of the passage of enriching solu-

[3] U. S. G. S. Bull. 529. Page 186.
[4] Memoir No. 77. Geol. Sur. Canada.

tions to great depths. Silicification of limestone by contact metamorphism will also allow of the development of chalcocite, as at Bisbee.

All this we shall have to accept, referring the reader to the many papers and publications on secondary enrichment for further information.[9] We assume that the solutions have done their work and have mingled with the great water-zone below ground-water level. It is constantly changing, as we have seen. The enriched sulphides are subject to an aftermath of oxidizing influences and there is a rearrangement, a new distribution of the copper content. The most common changes are those that result in the formation of oxides or the native metal. While not an invariable rule, the presence of native copper or the oxides of that metal is a sign of the alteration of secondarily enriched sulphides and de-

BUCKEYE OUTCROP, GLOBE, ARIZONA.

notes long continued erosion. I do not include the Lake Superior copper deposits in this generalization. They are of an entirely different character.

In the description of the zonal arrangement of metallic products, the not infrequent presence of a belt of oxy-sulphides was noted. This will be more pronounced as erosion proceeds, with decreasing quantities of sulphides, but with proportionate increase in the richness of the copper contents of oxidized products.

Cuprite is characteristic of the original deeper zones of oxidation in the vicinity of the secondary sulphides. It occurs both in an amorphous earthy condition and in beautiful crystalline form. At the Ray Central mine, the upper envelope of the disseminated chalcocite is characterized by chalcotrichite, the acicular form of cuprite. This same mineral is found with cavernous limonite in the Moctezuma mine at Morenci. At the Chino mine, I have observed a blood-red train of cuprite coming off the concentrating tables, testifying to its association with the chalcocite ore. At Butte, while not common, I have seen it in association with native copper above the richer chalcocite stopes. At Bisbee, in the Hoatson mine of the Calumet & Arizona, it is abundantly developed and native copper often replaces cuprite cubes. It is connected directly with the enriched sulphide ores. Hence my statement that it is an indicator of the second cycle in the chemical changes that take place, the oxidation of the enriched sulphides as they are exposed to the constant attack of meteoric waters.

Native copper seems to be the ultimate product of this long list of progressive impoverishment, enrichment, and concentration. It is the last stage of Nature's hydrometallurgical process. From the inappreciable quantity of the metal brought up from below by igneous rocks, by devious and varied routes, by many agents, by many steps, through long intervals of time, Nature at last turns out a product 100% pure. Surely the old earth is a great workshop.

Testing Detonators

A detonator is a blasting-cap, or copper capsule containing a small quantity of some explosive compound that is ignited by a fuse. An electric detonator is one that is ignited by a small wire that becomes heated to incandescence, or fused, by the passage of an electric current. Fulminate of mercury is a well-known detonating agent. It may be mixed with 10 or 20% of potassium chlorate, and tests have shown that the fulminate alone is inferior to a 90:10 mixture, which in turn is inferior to an 80:20 mixture. The U. S. Bureau of Mines employs 'sand-tests' for testing the relative efficiencies of detonators. A uniform clean quartz sand of 30 or 40-mesh is employed. The sand is placed in a small steel case, which has thick walls and a cover. The detonator is fired in the centre of a mass of 100 grams of standard sand placed within the cavity. The extent to which the sand is pulverized by the detonation, as measured by screening tests, indicates the efficiency of the detonator. It has been assumed that a high speed of detonation is an essential property of a detonator. This is not so. Many explosives, such as blasting gelatines and nitro-glycerine, have a higher velocity of detonation than fulminate of mercury, but they have not the properties that fit them for use as initial detonators. It appears that the explosion of mercury fulminate results in an intense local action in the form of a sudden blow. Former methods of making tests, in which the detonators were fired in holes in lead blocks or their influence tried on other detonants at various distances, had proved unsatisfactory, the sand-test being now preferred for careful work. However, a simple test can be made with a 4-in. wire finishing-nail. The detonator is fired in proximity to the nail, and the resultant bend in the nail indicates the strength of the explosion. The strength of fulminate detonators is said to be not affected by becoming moist, although detonators of trinitrotoluene are weakened by moisture. The T.N.T. detonators may become entirely unserviceable after storage for a month in a damp magazine.

Gold Mining in the Philippines

By C. M. Eye

THE Aroroy district on the island of Masbate furnishes the greater part of gold produced by lode mining in the Philippines. The Colorado is the largest of these mines. During last year 50,000 tons of ore was treated at this mine, with a yield of $425,000 in gold at a net profit of $230,000, or 46% on the capital. Two dividends each of 10%, were paid during the year, and an undivided profit of $325,000 was on hand at the end of the year. The mine has an ore reserve of an average grade of $9 per ton, in quantity sufficient for five years. The stoping width is 16 to 20 ft., and in a new ore-shoot it will be as much as 36 ft. of $14 ore. Waste for filling is let down through chutes from surface. It is likely that an electric haulage system will be installed.

Several changes have been made in the mill. At present only 20 hours of contact with the cyanide solution is necessary, and assays of pulp from the classifier following the tube-mills average only $1 per ton on $9 ore. This has made possible the elimination of agitation, the pulp being passed from the classifier to thickeners, the overflow going to precipitation, and the underflow to another pair of thickeners in parallel, thence, with the solution of $1.60 per ton, to leaf-filters, from which it is discharged with about 20c. loss in soluble gold, and 80c. in insoluble. The overflow of the secondary thickeners is also sent to precipitating-boxes, and the entire barren solution, with the washes from the filter, is sent to the head of the mill. The mechanical changes include the installation of shaking-feeders in the chutes to the stamps for removing fine below about ⅜-in., and passing this fine directly to the classifier; an addition of another 5 by 16-ft. tube-mill to the original battery of two; the substitution of steam-pumps for the triplex pumps originally used; the replacement of revolving-drum filters by a leaf-filter, and the changing over from steam to an internal-combustion engine for furnishing power for the main operations. The depletion of available manglar wood has made it necessary to use other fuel as the main source of power, so a 500-hp. engine of the Diesel type has been purchased. Fuel-oil suitable for this engine is delivered in drums from ships in the bay, a mile from the mill. Wood costs $3.25 per cord, delivered, but the quality has diminished in value, as the best manglar wood has been exhausted. At the beginning of operations, a cord of this wood weighing 3000 lb. had a fuel-value of at least 12,000 B.t.u. A change proposed is to remove the crusher from above the mill-bin, and set it higher, using a revolving screen below it to remove the fine. Such a screen has been tried, but is not now in use, probably from lack of head-room. Considering the sticky character of the fine, it would seem better to install a washer, as mentioned later in connection with the Syndicate mill, for the better reduction of the coarse portion of the ore, much of which is extremely hard.

The Colorado company is developing other promising veins and has several properties under option on which it is doing development, spending in exploration $1000 per month. These outside veins are mostly of what is termed in California 'bull quartz' the gold being apparently in a coarser form than in the main veins, so it is likely that if extensive orebodies are found, amalgamation will be a feature of the treatment.

The Syndicate mine is next in importance. It is equipped with a good mill, which treats 120 tons of ore per day. The ore from the mine is freed from fine in a revolving trommel by a wash of cyanide solution, the fine being carried to the classifier, while the coarse goes first to a Blake crusher, thence, after passing over a grizzly, to a roll-jaw crusher. The crushed product goes to a Hardinge ball-mill, taking inch material and delivering maximum particles of ¼-in. There is also a Hardinge pebble-mill, and a 6 by 16-ft. tube-mill for final reduction of the sand from the head of the Dorr classifier. The finished product goes to a set of primary thickeners, the overflow of which goes to zinc-boxes, and the underflow to an agitator built after the description by Whitman Symmes that appeared in the Mining and Scientific Press of July 19, 1913. From this agitator the product goes to secondary thickeners, and thence to two Kelly filters. The final loss in dissolved gold is about the same as at the Colorado mine, namely, 20c. per ton. The average grade of ore handled is better than at the Colorado, but it does not yield so easily to treatment. The extraction might be improved by longer contact and more agitation, the undissolved gold in the final discharge being, I believe, about $1.40 per ton.

Power is supplied by several internal-combustion engines of the Diesel type. A shortage of power to operate the various units, some of which take heavy loads intermittently, has hindered operations. Recently the operation of the plant has been handicapped by the wrecking of a 100-hp. Diesel engine of German manufacture, through crystallization and breaking of bolts on one of the crank-shafts; the inconvenience is aggravated by the fact that it is impossible to get duplicate parts from Germany. Fortunately, a 150-hp. Diesel engine of English make is on the way, a duplicate of one already in use.

The Syndicate mine near-by has a number of promising veins, and the condition of the mine is said to be good. Two dividends of 5% each were paid in 1915.

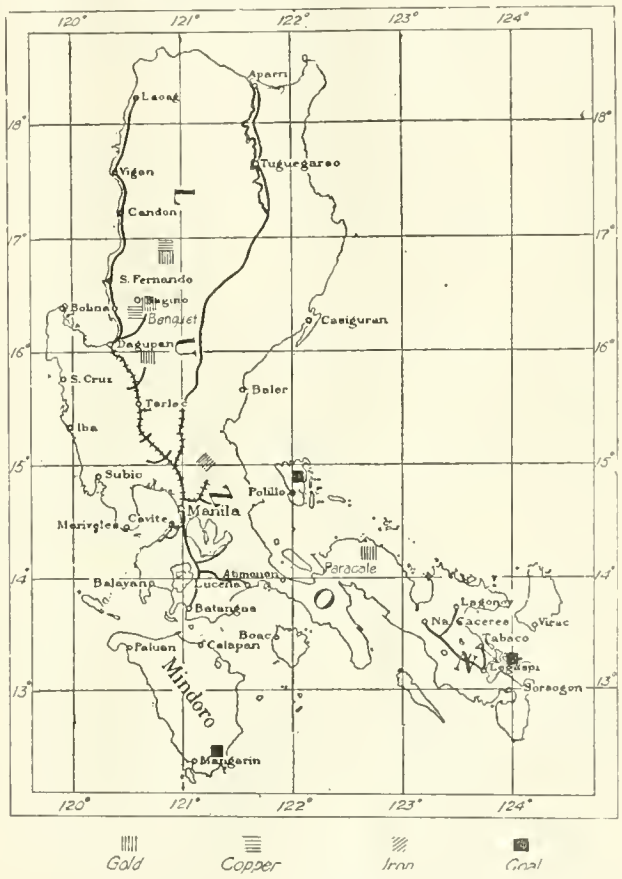
The Keystone is the next mine of importance. It is equipped with a mill for handling 50 tons of ore per day. It is kept in fairly steady operation, but, like the other

mills, has insufficient power. The motive power here is also derived from internal-combustion engines, and, as there are no filters in the plant, the load is fairly even. Therefore electrical conversion is not used, and the engines drive the machinery through line-shafting. The ore is delivered by a jig-back gravity surface tramway to a grizzly preceding a Blake crusher, whence, after passing over another grizzly, the oversize goes to a pair of rolls, 14 by 28 in. and thence to the storage-bin, where it joins the fine. Two Lane slow-speed Chilean mills are fed from the bins, delivering their product to a Dorr classifier, the sand from which, assaying $5 to $7 per ton, goes to four leaching-tanks, where it receives 36 hours of treatment, bringing the content of insoluble gold down to about a dollar per ton. The slime from the classifier passes to a system of thickeners where, by decantation, the treatment is finished without filters. There is also a 5 by 16-ft. tube-mill that on occasion is used to reduce sand to slime, returning the product to the classifier. But owing to shortage of power, it has been found necessary to bulkhead off about 7 ft. of this mill, converting it in action into a short mill.

The chief difficulty arises when the unoxidized ore, which is heavy in iron sulphide, is mixed with the oxidized ore, which is the main output. Mine developments show that the oxidized zone is shallow, so that, while the area to be explored is large, it is likely that the treatment will have to be changed considerably when the surface ore is exhausted. The mill is well placed as regards the future working of the property, and it is conveniently situated as regards handling of supplies, being near the beach on a cove of Aroroy bay. No dividends have been paid, but the outlook is much more promising than at any time in the past.

The Benguet district of northern Luzon ranks next to the Aroroy district in production. The new mill of the Benguet Consolidated Mining Co., which started in September, is running steadily and is furnishing the principal output. The ore at present assays about $20 per ton, the output for February being 1500 tons, yielding more than $25,000 in bullion. Power is furnished by a 100-kw. hydro-electric plant, using the water of Antamok river under a 320 ft. head. At this time of year, trouble is experienced from shortage of water, but the rains will begin soon. Trouble has been had with tube-mill liners, and the failure of a locked type of boltless liner tied up the tube-milling for some time. Now, however, a supply of a superior type of lining ensures against a recurrence of this trouble. It may be remarked that operation of the plants at Aroroy has been delayed through the non-arrival of supplies from the United States.

The treatment given the ore is as follows: crushing to 2-in. maximum size, stamping through 8-mesh 'Reetang' screen to a Dorr classifier in a closed circuit with a 6 by 10-ft. tube-mill, passing the product of minus 100-mesh to a primary thickener; the overflow solution is precipitated and the underflow is lifted by diaphragm-pumps to a series of three Dorr agitators, at the head of which the solution is brought up to 3 lb.; thence to a series of four secondary thickeners where successive decantations are made, on the counter-current system, and final discharge at 1 : 1 with about 24c. in dissolved value, and one pound of cyanide per ton. In order to reduce the soluble loss, as well as to save cyanide, and allow of a fourth full decantation in the secondary thickeners, a Trent replacer of the Carpenter overhead-suspension type is being installed. The loss in undissolved gold has



NORTHERN PART OF THE PHILIPPINE ISLANDS.

been high thus far, owing to the presence in the richer ore of a high-grade sulphide of iron that does not yield its gold easily to treatment. It is probable that a special battery of three stamps will be installed, with a concentrating sand-table for handling the ore in which this high-grade sulphide occurs, the sand and slime from this mill being then passed to the classifier of the regular mill for treatment. The stamping will, of course, be done in cyanide solution of regular mill-circuit strength, in order to avoid dewatering.

An orebody recently uncovered is looking well, both on the milling level and on the level 100 ft. below. A square-set stope has been opened 160 ft. long by 20 ft. wide, the average grade along the sill-floor being $16 per ton. The continuation of the richer portion of this orebody to the north-west has been opened for 120 ft., showing a width of 3 to 5 ft. of ore assaying $75 per ton. It has not been determined yet whether this ore goes to surface, 200 ft. above. Altogether the outlook for this property is most promising. The width of the mineral-

ried one is about 100 ft. and the company holds patents over 3000 ft. on the outcrop.

The Headwaters mine, under lease to L. O. Hibbard, is the next largest producer in the Benguet district. The mill is operated as an amalgamating plant only, the stamps crushing through 40-mesh screen, the product passing over several sets of plates, thence to waste. As a rule, low grade ore is handled at small expense, and the recovery is fair. At present only five stamps are dropping, but the operation is said to be profitable. Of course, on a lease that has but a limited time to run, it is not likely that much development work of permanent value will be done.

The Acupan mine, on Batman creek, is the only other producer. The three light stamps, with arrastra following, are driven by water-wheel, and have been handling an accumulation of low grade, soft, free-milling ore with an output of $800 to $1000 of gold per month. The operating expense is light, and the profit is being applied to the development of a well-defined vein outcropping above the mill. A remarkable feature of this deposit is an appreciable quantity of cinnabar throughout. In the Lubang district, in the south-western corner of Benguet, there are several primitive mills working, but little is known regarding their operations, except the information given in the bulletins of the Bureau of Science. There may be other small prospecting mills elsewhere in the islands, of which I have not heard. It seems reasonable to assume that the output from mills treating gold ore will average $100,000 per month for 1916, putting the output of the Colorado at $40,000, the Syndicate at $25,000, the Consolidated at $20,000, the Keystone at $10,000, and all other mills at $5000 per month. There are no new mills being erected, but it is probable that most of the existing plants will increase their output, and none are likely to close down. A number of promising prospects are being opened in the Benguet district and elsewhere, but none that are likely to need new mills during the present year.

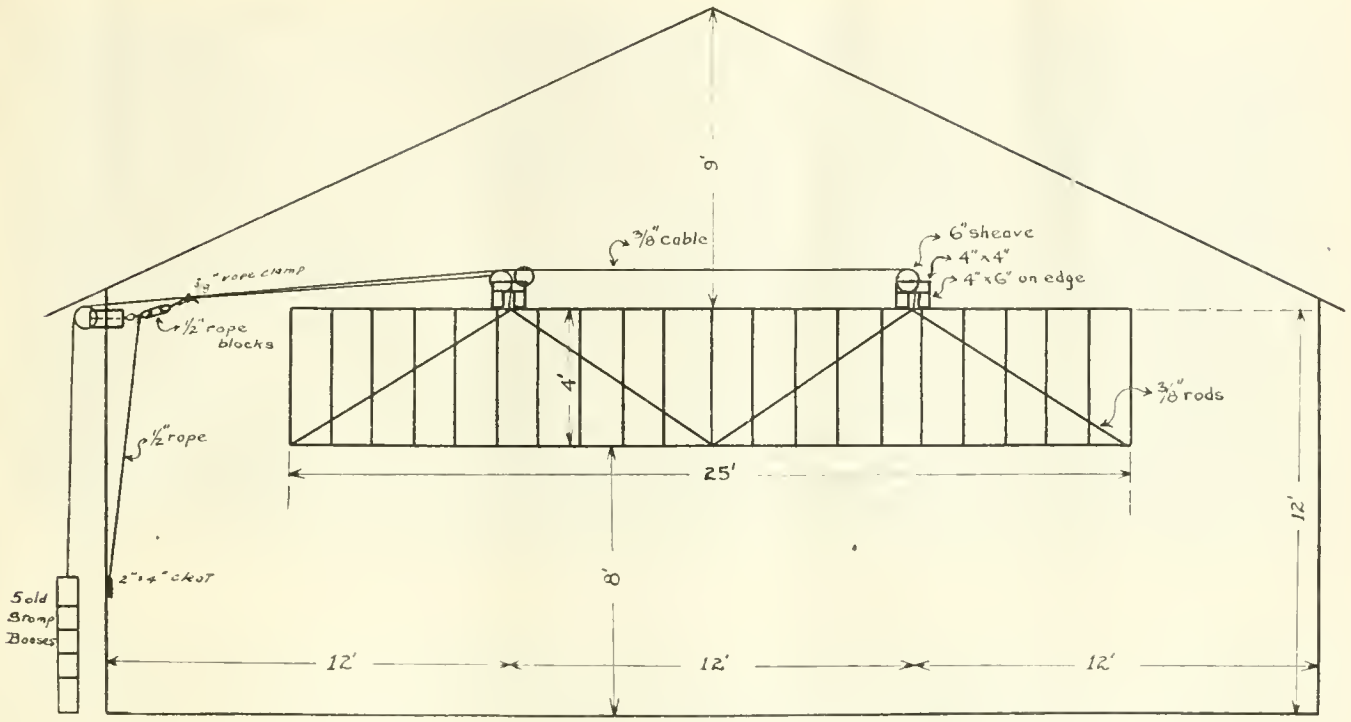
As regards the political situation, the general opinion among local mining men is that the policy of the Government will not be discouraging. In case independence is granted, mining will suffer somewhat, in common with other industries from the increased taxes and decreased efficiency of administration, yet it will be little worse than at present, with an administration entirely pro-Filipino and the welfare of the islands a political pawn in the game of politics at home. Many wealthy Filipinos are investing in mining stock, but it is not an industry that they can develop themselves.

MINING in the war areas of Europe will suffer for a long time. For instance, when the Russians retreated from Galicia they greatly damaged a number of the oil-wells before relinquishing them to the Germans. Again it is reported that the German administration of the Belgian and French coal and iron mines is hurrying out coal and ore with no regard for the future conditions of the workings.

A Wet Shaft

In opening the Leonidas mine at Eveleth, Minnesota, a great deal of trouble was caused by the heavy flow of water. A large vertical shaft was sunk, and lined with steel members; planking was used for temporary lathing, and replaced later by reinforced concrete slabs. Glacial drift, 72 ft. thick, covered the rock, which was taconite, a hard silicious formation, more or less broken. Water was found at 30 ft. depth, and the flow became so heavy at 268 ft. that a temporary pump-station and sump were cut and three Prescott pumps placed there. Four sinking-pumps were employed to 'shamble' water to them. At that time 1500 gallons per minute was being handled, this flow being entirely in a shaft with no levels developed. The miners were usually working in a foot or two of water, with more water pouring upon them. By the time the shaft was 356 ft. deep, 2400 gal. per minute was being pumped; this required six sinking-pumps in the shaft, one of which pumped directly to surface. So rapidly did the flow increase that it was necessary to cut another temporary pump-station at 348 ft. Four pumps were put here, two of which were taken from the 268-ft. station. This equipment served to complete the shaft, 100 ft. deeper, although at times the flow ran as high as 3500 gal. per minute. When the permanent pump-station was being cut, the flow was 4000 gal. per minute. During this work a Cameron pump and one of the sinking-pumps were put in the entry, both of which discharged to surface. The large number of pumps made the shaft uncomfortably warm. A permanent pump-house of steel and concrete-slabs was built at 438 ft. depth, broken rock being filled between the concrete-slabs and the solid rock. Before this lining was erected, it was almost impossible to see from the centre to either end of the pump-house on account of the torrents of water falling. After the double-pitched roof was erected the room was practically dry. The permanent pumps installed were two 16 and 32 by 8 by 36-in. Prescott, corliss, cross-compound, crank-and-fly-wheel units, each with a normal capacity of 1500 gal. per minute and a maximum capacity of 2200 gal. per minute against a head of 450 ft. This type is economical of steam; its guaranteed duty is 135,000,000 foot-pounds of delivered work per 1000 lb. of dry steam consumed (of 125-lb. gauge pressure), the vacuum being 26 in. of mercury. Each pump is supplied by a 5-in. steam-line and discharges into a separate 14-in. pipe. The pipes can be cross-connected, so that either engine can take steam from either steam-pipe and discharge into either column. An auxiliary pump is also set in the entry for use in emergency.

CEMENT PRODUCTION of the United States in 1915 amounted to 85,914,907 bbl., a decrease of 2.6%. Stocks at the end of the year were 11,781,166 bbl., a reduction of 7.8%. The average price at factory last year was 86c. per barrel, ranging from 69.9c. in Pennsylvania to $1.375 in California.



SECTION OF DRY-HOUSE, SHOWING ARRANGEMENT FOR RAISING AND LOWERING LOCKERS.

A New Dry-House

By R. E. Tremoureux*

A new dry-house was built at the Champion mine, Nevada City, California, in November 1915, to accommodate 320 men, at an approximate cost of $8 per man. The house is built on a level waste-dump, with concrete walls four inches above the floor-level. The floor contains 2160 square feet of concrete put in at the following cost per square foot:

Labor	$0.044
Supplies	0.069
Total	$0.113

The floor is built with a grade to the centre of the shower-baths. The building is 36 by 60 ft. and 12 ft. high, with a 9-ft. rise in the roof. The building contains 5254 board-feet of lumber, built at the following cost per M board-feet:

Labor	$14.80
Supplies	21.20
Total	$36.00

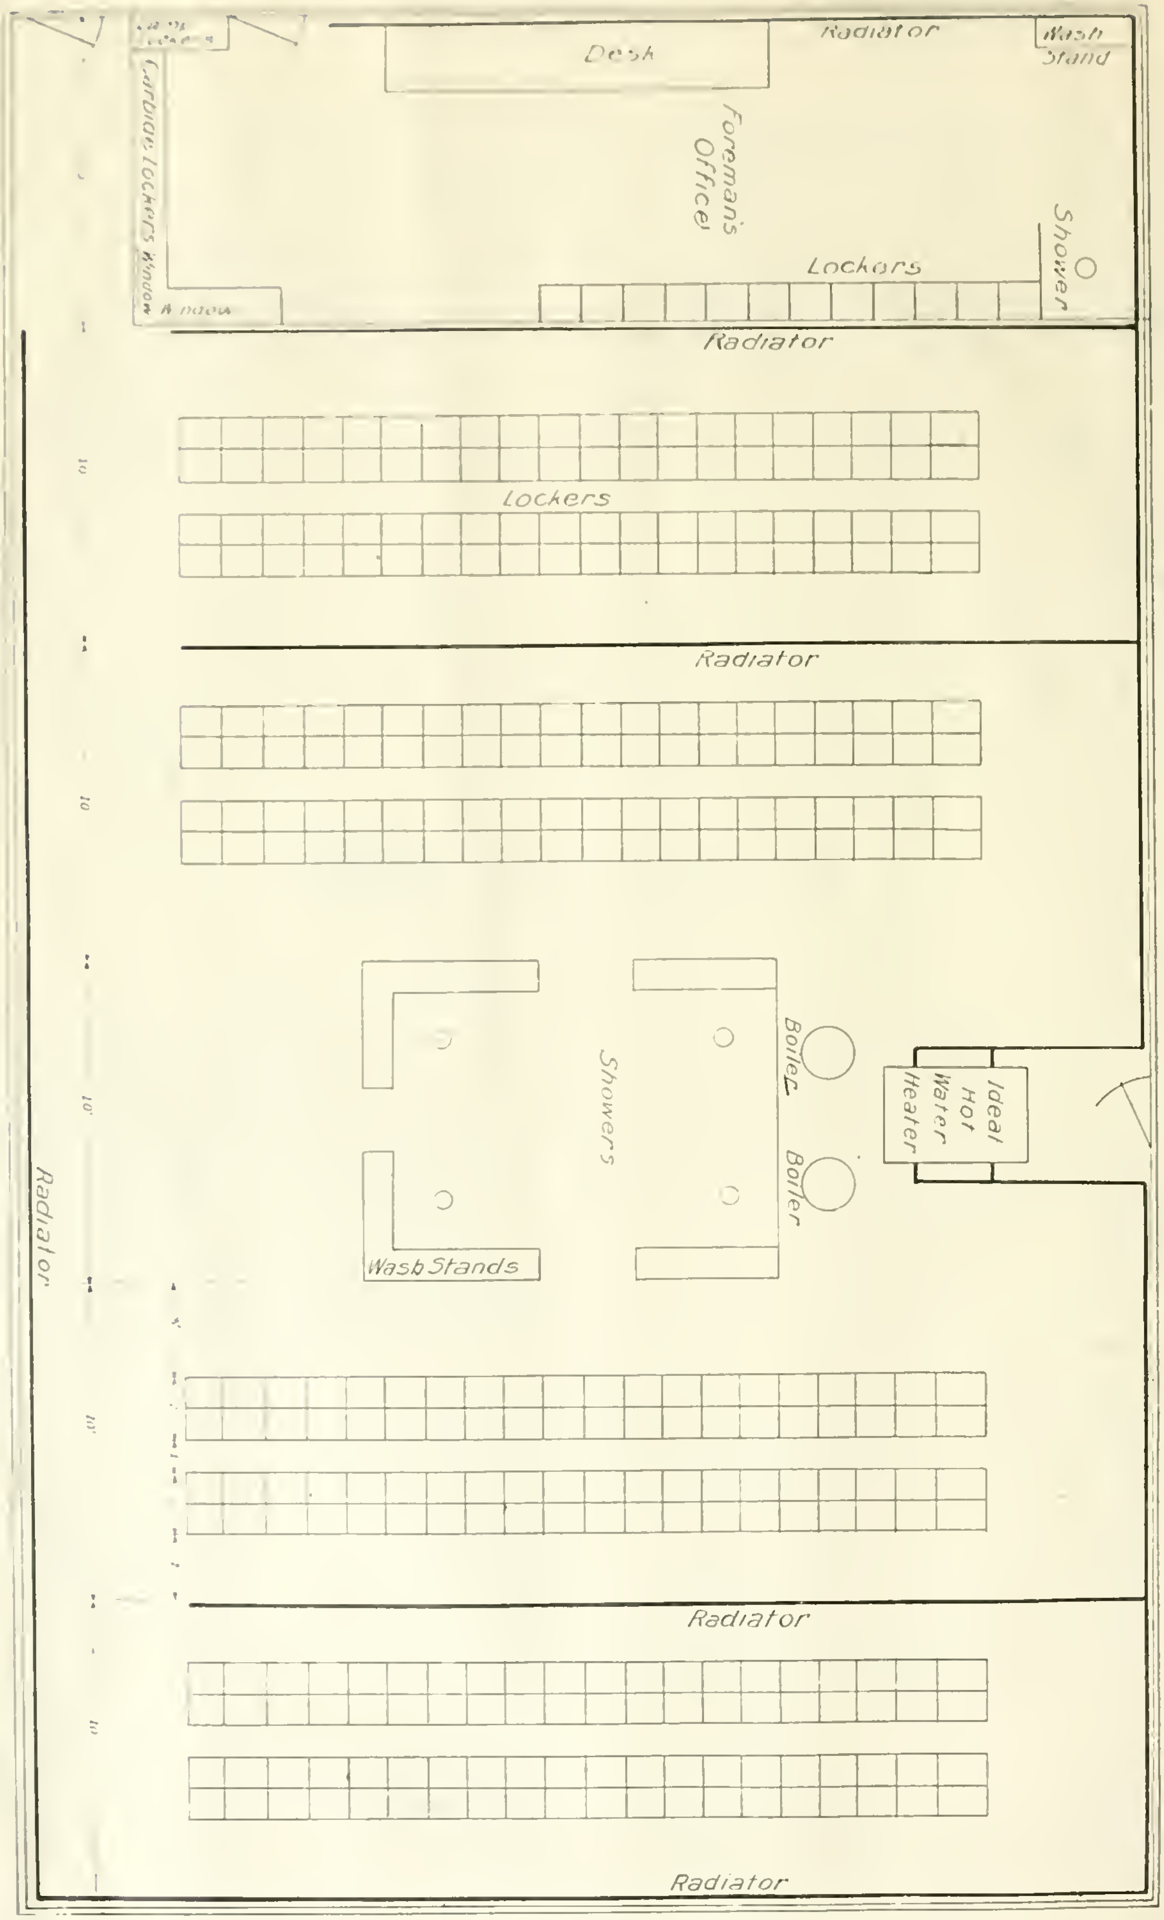
The roof and sides, having 5407 square feet of outside surface, including doors and windows, cost per square foot:

Labor	$0.008
Supplies	0.143
Total	$0.151

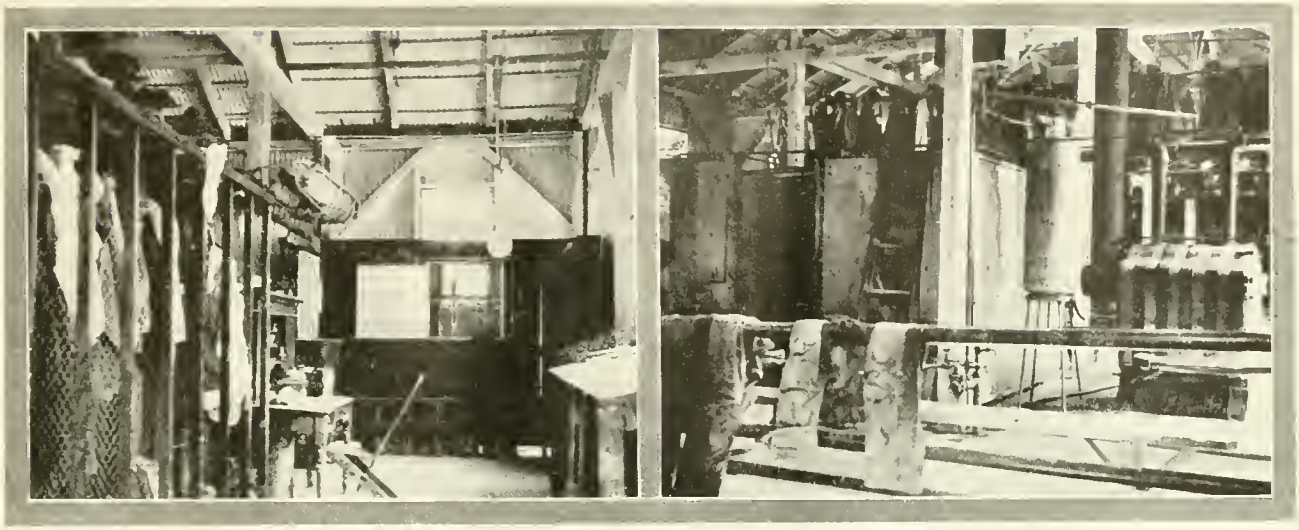
*Assistant superintendent, North Star Mines Co., Grass Valley.

The house is built to contain 8 sections of suspended lockers, each locker containing 40 compartments. The lockers are counter-balanced on the outside of the building and can be raised and lowered easily by one man. When raised, the bottom of the locker is eight feet from the floor. There are four showers in the main room and one in the foreman's office. The wash-stands are built along the sides of the showers. The dry is heated through 2-in. pipe-radiators, by an Ideal hot-water boiler. The total summarized costs are as follows:

	Labor	Materials and supplies	Total
Grading	$ 19.50	.....	$ 19.50
Concrete walls	19.13	25.50	14.63
Concrete floors	93.75	149.55	243.30
Building	77.75	111.39	189.14
Roof and sides	41.50	779.08	820.58
Windows and doors	29.00	1.06	30.06
Lockers	217.50	237.84	455.34
Ideal boiler erection	12.63	200.30	212.93
Boiler radiators	103.75	120.55	224.30
Hot-water boiler	13.37	20.80	34.17
Electrical work	20.98	10.00	30.98
Showers	25.38	41.22	66.60
Foreman's office	11.75	7.50	19.25
Pipe work	20.62	36.65	57.27
White-washing	24.50	3.20	27.70
Sundry	38.75	2.63	41.38
Superintendence	60.00	.....	60.00
Totals	$829.86	$1747.27	$2577.13



PLAN OF CHAMPION MINE DRY-HOUSE, NEVADA CITY, CALIFORNIA.



VIEWS INSIDE THE DRY-HOUSE AT THE CHAMPION MINE, SHOWING LOCKERS AND HEATER.

The lockers are made with ¾-in. pipe and rail fittings, forming a rectangular frame 4 by 25 ft., divided into 20 small rectangles 4 ft. by 15 in. The compartments are made by screwing 12-in. pipe-nipples into the corners of the small rectangles and on both sides of the main frame. The 40 compartments, 4 ft. by 15 in. by 12 in., thus formed, are separated by wire-netting. Round iron rods, ⅜ in. diam., made with an eye on one end and threaded on the other end, are used to brace the lockers to the two points of support. The eye slips over the ¾-in. pipe and the threaded end goes through an iron plate, with an eye riveted in the centre of the plate. A ⅜-in. wire-rope clamped through the eye in the plate runs from the right-hand support over a sheave directly over this point of support, then over a sheave over the left-hand support, then over a sheave on the wall-plate of the building. The weights are hung on this rope. A shorter ⅜-in. wire-rope, clamped to the eye in the left-hand support-plate, runs over a sheave directly over this point of support, and is then clamped to the rope from the right-hand support. A loop is left, where the two ropes are clamped, for the ½-in. rope-blocks to fasten to. An eye-bolt in the wall-plate of the building takes the other end of the rope-blocks. When the lockers are raised the end of the ½-in. hemp rope fastens to a cleat on the side of the building.

Hiring, Handling, and Firing Men

By E. F. Irwin

*After being in charge of the Employment Department of the Homestake Mining Company for 14 years I feel that if I could put the results of such experience in suitable words it would be of inestimable benefit to the students ready to begin active work in the mining world. An education along technical lines generally misses one of the greatest problems of success in mining, the human element, the handling of men. Two-thirds of the money spent in mining goes for labor. To get the best there is for that money means the study of human nature, to become acquainted with the men applying for work, and to be able to pick and choose so that the result will be a force of efficient, intelligent, and ambitious men.

I put efficiency first. To get the work done and done well, the first question is whether the applicant is physically sound and has a reasonably long life ahead of him. Working in mines is hard work at the best and it would be poor judgment to hire a man who has given the better part of his life to previous employers. Look to the future as much in judging physical qualifications as in mental.

Intelligence is so obvious that it needs not be dwelt upon, only that in employing day laborers one is apt to think the bigger the man the more work he will turn out, losing sight of the fact that he may never be able to take a position above the pick and shovel and thus you are closing one place where an intelligent man would profit by the experience and be made into a skilled workman, ready to go higher when needed.

Ambition in a man is worth more than any other qualification. It is the spur that constantly goads him on, making hard work and poor surroundings bearable, when he knows that overcoming such obstacles better fits him for the positions higher up. Ambition fosters determination and an iron will that never admits failure. When a man says he is willing to do anything to get a start he will make a good man anywhere. Encourage

*From the *Pahasapa Quarterly*, published by the South Dakota School of Mines.

ambition in your men by promoting the most efficient, thus showing other employees the reward to be gained by ambition regardless of length of service.

Hiring men is a constant study of human nature. Talk to an applicant, ask him questions, draw him out to talk of himself. If he has been wandering all over the mining world, and is anxious to tell how many different places he has worked, he will not make a steady employee, not worth keeping a steady man out for. Do not depend on first impressions as to shifty eyes, nervousness, or inability to talk fluently. Some of the best men's eyes are constantly moving while they are talking, and many a rogue cultivates a steady gaze. In asking questions rapidly no man can deceive you long. You will see his mental activity in making up answers showing in a hesitancy of speech, a mental grouping of the best things to tell and what to conceal. Weigh all these things in your mind before judging and do not let prejudice influence you too much. While the man does not impress you very favorably he may have good qualities that can be brought out and cultivated. Hard luck stories denote an unstable man. The man who must have work immediately or starve usually is telling the same story to another mine official in another state in thirty days.

Be optimistic. Overlook the minor faults and try to bring out the good points in your men. Every man will respond to encouraging words, while sarcasm and short, ugly tones in giving orders antagonize the men. Do not try to impress men with your authority. The fact that you are in charge is sufficient evidence that you are 'boss.' To illustrate this point: A party of sightseers, among them some young ladies, were visiting a large rock quarry. They were very much interested in the work, the machinery, the blasting, and other things. After the trip one gushing young lady addressed the foreman:

"Mr. Flannigan, this is wonderful, wonderful; but how is it kept going; who looks after it all; who is the boss here?"

"I am ma'am."

"Indeed, but it does not seem possible."

"Do you doubt it? Jimmie, come here! (Jimmie comes.) Ye're fired."

So Jimmie, in order that the lady might be shown who is boss, is out of a job and a new man has to be employed and broken in to take his place.

Every man employed should be watched and studied carefully, to see if he comes up to your estimate of him, and if not, make a mental note of where you were mistaken in hiring him and avoid it in the future. Be enthusiastic in your work; get that spirit among your men, and your future in the mining world is assured, even though you were not at the head of your graduating class.

When you have employed a good working force use your best endeavors to hold them together. Do not conclude, if a man quits or is discharged, you can easily get another. You lose on every change. Breaking in new men costs money. If the man you lost was a good man your chances of getting another good one to take his place are about one in five. In other words, you will hire five average men to get one thoroughly dependable. This may sound contradictory, when you have used your best endeavor to hire good men, but good men are always in demand. They are kept when hired and the floating class you get your men from are usually the ones from other places where they failed to make good.

The social welfare of your men is just as important an item as the machinery to work with. Laborers must have diversion. The periodical drunken carouse was formerly, and, as much as we regret it, is today to some extent, the diversion of miners. But it is being replaced by means of recreation. The Homestake company has a large recreation building containing a library, theatre, pool and billiard room, bowling-alleys, gymnasium, restroom, and swimming-pool, and it is a good investment. The men are better for it, and some way of diverting the men's mind from the continual grind of daily work should be provided at every mine.

Bear in mind that hiring is the first, handling second, and 'firing' last and least. Good hiring and handling leave little cause for 'firing.' Finally, when you have to discharge a man talk to him plainly and frankly. Try to have him understand where he failed, as you see it. He may profit by the talk, and the plain statement of it from your point of view makes a better man of him when he starts again. When 'firing' do not consign him to the job of everlasting firing in the hereafter. He may make good elsewhere and then you will regret your failure to make a good employee of him while you had the chance.

Summing up: "Do unto others as you would that they should do unto you."

Dredging in Colorado

At Breckenridge in Summit county three boats are operated by the Tonopah Placers Co., a subsidiary of the Tonopah Mining Company of Nevada. During the year ended February 29, 1916, the following results were obtained:

Ground dredged, cubic yards	3,242,247
Ground dredged, acres	53.175
Ground remaining undredged, acres	4,782,918
Gold recovered, ounces	23,034
Silver recovered, ounces	5,416
Value, cents per cubic yard	11.7
Cost, cents per cubic yard	6.1
Operating profit	$211,693
Dividend paid (initial of 5%)	50,000

SHIPPING DIFFICULTIES, from lack of ships, and the extraordinary increment in the rates for ocean freight is indicated graphically by the fact that for long voyages such as from New York to Chile or from San Francisco to Japan, the cost of chartering a steamer for a single trip is now as much as the purchase price of the steamer before the War.

Ozokerite in Utah

By L. O. Howard

INTRODUCTION. Ozokerite, although brought into the daily life of millions of people, is a rare hydrocarbon found commercially only at Boryslau, in Galicia, and in eastern Utah. It is associated with bituminous shales and sandstones, clay-schist, gypsum, and salt, usually near petroleum springs. The chief use of it is for the production of ceresin (or white wax), although the poorer varieties are distilled for liquid hydrocarbons. The color of ozokerite is from transparent yellow or greenish, in the finest varieties, to black. The best grade can be easily kneaded. The crude Galician is scaly and waxy, with resinous fracture, brittle, and hard as beeswax. Friction induces a negative electric charge and produces an aromatic odor. Inferior varieties are black and soft, or hard with a fibrous structure and conchoidal fracture; others have the hardness of gypsum and are dichroic, transmitted light being yellow, and reflected light dark-green.[1] The melting-point is between 58° and 100°C.

The Utah mineral is semi-brittle, slightly friable, cuts easily but does not adhere to the knife, cannot ordinarily be worked between the fingers, and is black, with occasional brown resinous portions. The melting-point varies from 54°C. (for an entirely black material with a pronounced petroleum odor, easily molded, and soluble in boiling ether) up to 65° (for a pure variety, usually yellow, completely soluble, and with a faint odor) and to 70° for the Colton product, which is incompletely soluble and odorless. The greater softness and lower melting-point of some specimens is caused by a larger content of bitumen and asphalt.[2] Where an excessive amount of bitumen is present, the ozokerite is of little value. Many reported discoveries have had this defect.

THE GALICIAN DEPOSITS. These are in the Carpathians at Boryslau, a town 40 miles south-west of Lemburg. In 1821 the first licenses were granted for working ozokerite or 'mountain tar,' but the important discovery was not made until 1854. The first distillation for the production of paraffin was in 1862. Numerous shafts were sunk by individuals, and in the '60s all the aspects of a mining boom were exhibited. Jocinsky estimated the number of shafts in 1865 at 5000 to 6000 for a total output of 2250 tons. In 1881 production had risen to 10,000 tons per annum. The number of operators decreased later although the production reached a maximum of 12,300 tons in 1885. This was limited to an area of 240 acres. Stealing was common, some estimates placing the amount thus taken from 1862 to 1890 as worth $1,200,000.

About 1885 the Government regulated the industry. A Viennese bank was given a practical monopoly. The production from 1898 to 1901 is stated as 18,248 metric tons, declining from 7759 tons in 1898 to 2707 tons in 1901.[3]

Galloway has given an interesting description of the origin, occurrence, mining, and refining of ozokerite at Boryslans, where it occurs in Miocene strata, from the surface to depths below 1500 ft., in association with petroleum. He states: "Ozokerite has obviously been deposited from petroleum during the flow of the liquid from the surface over beds lying at a greater depth than that in which ozokerite is now found."[4] The decreasing temperature of the oil caused the wax to precipitate near the surface in the form of scales, sheets, and masses, in the interstices of débris, sometimes embedding huge blocks of stone. Some liquid petroleum flows through the drifts, and ventilation must be carefully watched to avoid disastrous accumulations of the explosive carburetted hydrogen, which is given off in large amounts.

The ozokerite is found in three veins, one of which is 30 ft. wide, and is crossed at right angles by two others, 4 to 5 ft. wide. An attempt is made to sort the mineral underground. The waste is hoisted in sheet-iron cars, run upon a tipple and dumped into chutes from which other cars distribute it on the dump. The low-grade material goes to a second tipple and thence by chute to the melting-house. The high-grade is taken to a locked room, where two men sort it into two classes, for melting. The re-sorted high-grade is dropped through chutes to one set of melting-pots, the lower-grade joining the second-class from the mine. The different classes are melted in water in cast-iron pots, the purer material requiring less water than the lower grade. There were 46 of these pots, 4 ft. diam. by 3 ft. deep, to which heat was applied by flues passing underneath. The 'pulp' separates into three layers: melted ozokerite at the top, silt and waste at the bottom and water between. The ozokerite is ladled in 1½–2-gal. cans into wooden launders delivering to two wooden vats, 8 ft. diam. by 7 ft. deep, in which the sediment is allowed to settle more thoroughly. The purified ozokerite is cast in iron molds, which are 2 ft. deep and taper from a diameter of 12 in. at the top to 10 in. at the bottom. After cooling, the cakes are dumped and marketed. The second-class material receives two treatments of this kind, being added to the high-grade after the initial purification. The works are closely guarded by fences and gate-keepers.

[4] W. Galloway, South Wales Institute of Engineers, Proceedings for 1902-1904, page 223.

The Utah Deposits are near the north end of the Wasatch plateau in Utah county, near the D. & R. G. railroad, 90 miles from Salt Lake City. The belt has a northwest trend, extends 11 miles and is as much as two miles wide, the southern boundary closely paralleling the railroad from a point east of Colton, up the valley of the Price river to Soldier Summit, and down the west slope of the range.

The economic deposits are in sections 13, 14, 15, 22, and 25, T 11 S, R 8 E, and section 30, T 10 S, R 8 E, and sections 20 and 21, T 10 S, R 7 E. The pioneer work was done by R. J. Kroupa in 1886. Five mines were equipped and three separating-plants erected. The three principal showings are near Colton on the north side of the Price River valley; just east of Soldier Summit; and near Media station, on the north side of the canyon close to the source of Soldier creek, west of the summit. Soldier Summit is 7 miles north-west of Colton, and Media is 3 miles west of Soldier Summit. Colton and Soldier Summit are in the broad flat channel of the Price River valley.

Taff and Smith in 1905 published the only geological information that has yet appeared. The deposits occur in limestone, shale, and shaly sandstone in the lower part of the Tertiary deposits of the Wasatch group. Woodruff and Day give a section of the Eocene 25 miles south-east of Colton. At the bottom is the Wasatch formation, 1000 to 4000 ft. thick, consisting of sandy shale, and sandstone of irregular deposition and variegated colors. Overlying it is the Green River formation, the lower member, 1000 to 1125 ft. thick, consisting of sandstone, shale, and oölite, the sandstone occurring in beds 1 to 15 ft. thick. The shale is sandy, locally calcareous or bituminous, and evenly bedded. The middle member, 100 to 700 ft. thick, consists of thin beds of shale, some of them bituminous, and thin beds of calcareous sandstone. "This member is remarkable for the uniform thin bedding and for the large amount of bituminous matter which some of the beds contain."[1] The upper member is a thick-bedded sandstone, sandy shale, and clay-shale, 500 ft. thick.

Accepting the stratigraphy of Taff & Smith and Woodruff & Day, it is evident that the ozokerite beds are in a formation just below that including the great oil-shale deposits of eastern Utah. The association is suggestive. So far as known, ozokerite does not occur in the immediate vicinity of the oil-shale. The association of Galician oilfields with the Boryslau ozokerite furnishes a possible parallel.

In Utah the ozokerite is found at various positions in the Wasatch formation. The shales are friable, the sandstones moderately soft, and the limestone beds thin and brittle. Limestone occurs both above and below the ozokerite. The beds are uniformly tilted at 5° to the north-east. So far as known there are no faults of great throw. Fissures and zones of brecciation and parallel jointing intersect the strata. In these fissures and interstices, ozokerite has been deposited in thin sheets and films, and locally as masses of some size. The faces of the fissures and brecciated portions generally show slickensides, as the ozokerite frequently does. The vertical displacement is, however, slight. The fissures and joint planes are almost vertical, bearing N 10° W near Colton and Soldier Summit. A half-mile west of Media is a fracture zone bearing N 30° W, and a half-mile north-east of the same station is one bearing N 60° W. Both are almost vertical. The thickness of the deposits is variable, both vertically and horizontally. All of the deposits are within two or three miles of the railroad, with good wagon-roads and easy hauls.

At Colton station a shaft was sunk 110 ft. on a vertical shear-zone, 5 to 6 ft. wide. Drifts were driven at 15 ft. deep and at the bottom. Ozokerite occurs as scales or thin veins. Only a small production was made here.

Near the south-west corner of section 13, T 11 S, R 8 E, 1½ miles north-east of Colton, is a different fracture-zone, 500 ft. higher in the strata. At the time of Taff and Smith's examination, development consisted of an adit driven 225 ft. N 10° W on a shear-zone 4 to 6 ft. wide. From the end of this adit a drift was run 125 ft. east. At a point 65 ft. east of the adit a vertical fracture-zone was crossed. A shaft had been sunk at the mouth of the adit to a depth of 100 ft., and north-south drifts run at 60 ft. Small quantities of ozokerite were found here and there, as thin films along the joints. This property was developed further by the American Ozokerite Co. in 1912. It was known as the Pleasant Valley group, and consists of 12 lode-claims and a mill-site. The shaft was deepened to 180 ft., and a lower adit run 860 ft., or 640 ft. beyond the shaft. The upper adit was extended to 540 ft. This development resulted in the discovery of larger masses of ozokerite. In both the upper and lower adits the vein is 3 to 6 ft. wide. Ozokerite permeates the vein, sometimes in small lenses and sheets. The content varies widely, up to 15%. The zone has been traced about a mile, showing ozokerite distributed irregularly.

The rock was drilled with augers and a low explosive was used for breaking. All ore was taken out through the lower adit to the company's 30-ton mill. The property has been idle since 1912, but is fully equipped with power, shops, offices, and dwellings.

About a mile north of Colton near the north side of NW ¼ sect. 14, T 11 S, R 8 E, is the James Peak group of six claims. An adit follows a line of vertical fractures extending N 10° W, in which ozokerite occurs in thin sheets and small fragments. Prospects show the presence of ozokerite at various points along the zone. Other prospects that show the wax are in the SE ¼ SE ¼ sect. 14 and NW ¼ SE¼ sect. 15, and a limited amount of mining has been done in SW ¼ NW ¼ sect. 24, T 11 S, R 8 E, on similar north-south lines of fissured and jointed rocks.

The deposits at Soldier Summit are limited to the NW ¼ sect. 30, T 10 S, R 8 E, within a half-mile east and north-east of the station. This property has been

[1] Woodruff and Day. 'Oil-Shale of North-western Colorado and North-eastern Utah,' U. S. G. S. Bull. 581, p. 11.

acquired by the newly organized Wasatch Ozokerite Co. and is under development.

The mine is opened by a shaft 255 ft. deep, on a band of vertical fissures containing ozokerite, and by drifts at 44 ft., 98 ft., 140 ft., and 250 ft. The longitudinal section illustrates well the selective nature of the mining and the necessity for many working-faces. The ore is drilled with augers and broken by back-stoping. The ozokerite is found in veinlets in narrow fissures in the strike of the crushed strata and surrounding the brecciated shale and shaly limestones, with local swellings to 30 ft. Close and careful timbering is necessary. The 44-ft. level is extended to the surface and has been used as a haulage-adit. During the early development gas explosions were troublesome, so that it became necessary to obtain a better circulation of air. An air-shaft was put up from the 98-ft. level to the surface, and raises at frequent intervals now connect all the workings.

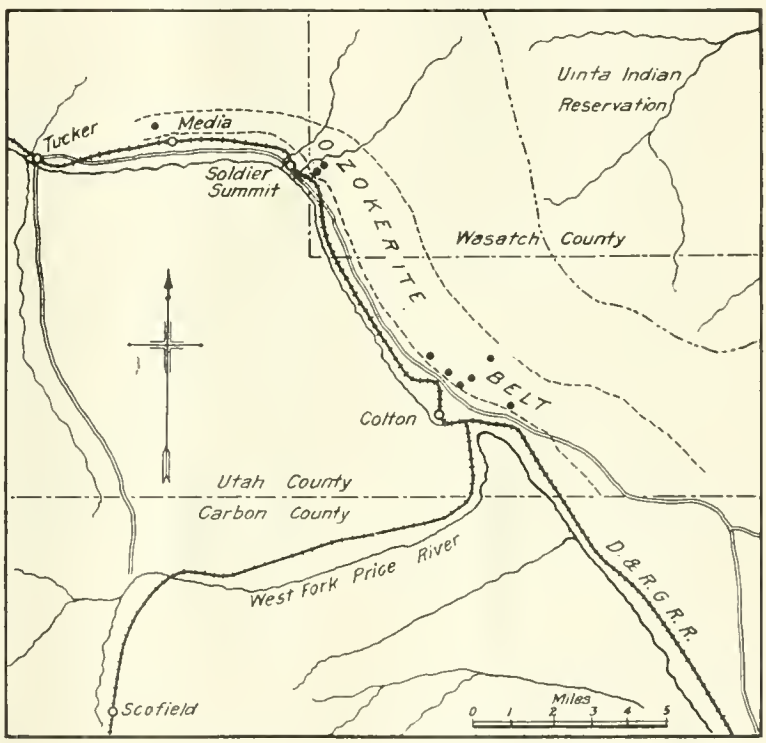
A 40-ft. head-frame is to be erected over the main shaft. Ore will be hoisted to the surface and trammed 70 ft. to the mill. Waste will be taken out through the 44-ft. adit and distributed on the dump below the mill. Development will proceed especially in the block of ground between the 140-ft. and 250-ft. levels, enough ore being anticipated from the upper levels to keep the mill operating at its intended capacity.

Two small mines have been prospected near Media in vertical fissures in shale. One is a half-mile west and the other a half-mile northeast of the station. The first zone is 2½ ft. wide and strikes N 30° W. The other is 4 to 5 ft. wide and strikes N 60° W. The ozokerite occurs in places here in the same way as at Colton and Soldier Summit.

Separating the Wax. The practice has been to crush the soft rock and ozokerite mixture, and deliver it to long narrow-bottom steam-jacketed vats with water at a temperature of 54 to 70°C. The wax melts and floats off to cooling-vats, the residue being moved along the bottom by a screw-conveyor. The plant of the American Ozokerite Co. was well equipped, but did not operate to the entire satisfaction of the company. It was situated below the lower adit. Ore was trammed to a 300-ton bin, from which it was fed over grizzlies having 1-inch apertures to a Gardner crusher having a capacity of 25 tons per hour. The fine material was fed automatically to two vats, in which it was agitated with boiling water. After agitation the pulp went to three long V-bottom vats in which the boiling continued, the molten wax being removed by 4-ft. skimming wheels delivering to two settling-tanks, where a further boil of an hour was given. In these tanks the remainder of the dirt was eliminated. The clean wax went to a 5-ton refining-tank for the removal of entrained moisture and was then cast into 10-lb. cakes for the market. Four grades were made, hard prime, high prime special, hard green, and soft wax.

The tailing was carried to the dump by a belt-conveyor. One of the difficulties of the process was the high fuel consumption owing to the large radiating surface. A boiler capacity of 85 hp. was used in the production of 1½ tons of wax per day. It was also found that the positive feed and discharge of the melting-vats was a drawback to efficient operation, giving no opportunity to regulate the discharge according to the condition of the residue. In the new plant nothing will move forward until its treatment in a particular portion of the apparatus is finished.

At the mill the ore will be dumped over a grizzly to a Williams crusher, set flush with the top of the fine-ore bin into which it will discharge. This bin will be 15 by 20 by 15 ft., with a V-bottom. The ore, crushed to ¼-in., will be delivered by automatic feeder to the first treatment tank, or 'digester,' a closed cylindrical iron tank, with conical bottom, 30 in. diam., and 6 ft. 1 in. deep over all. It is provided with a mechanical stirring device having four arms, and is steam-jacketed.

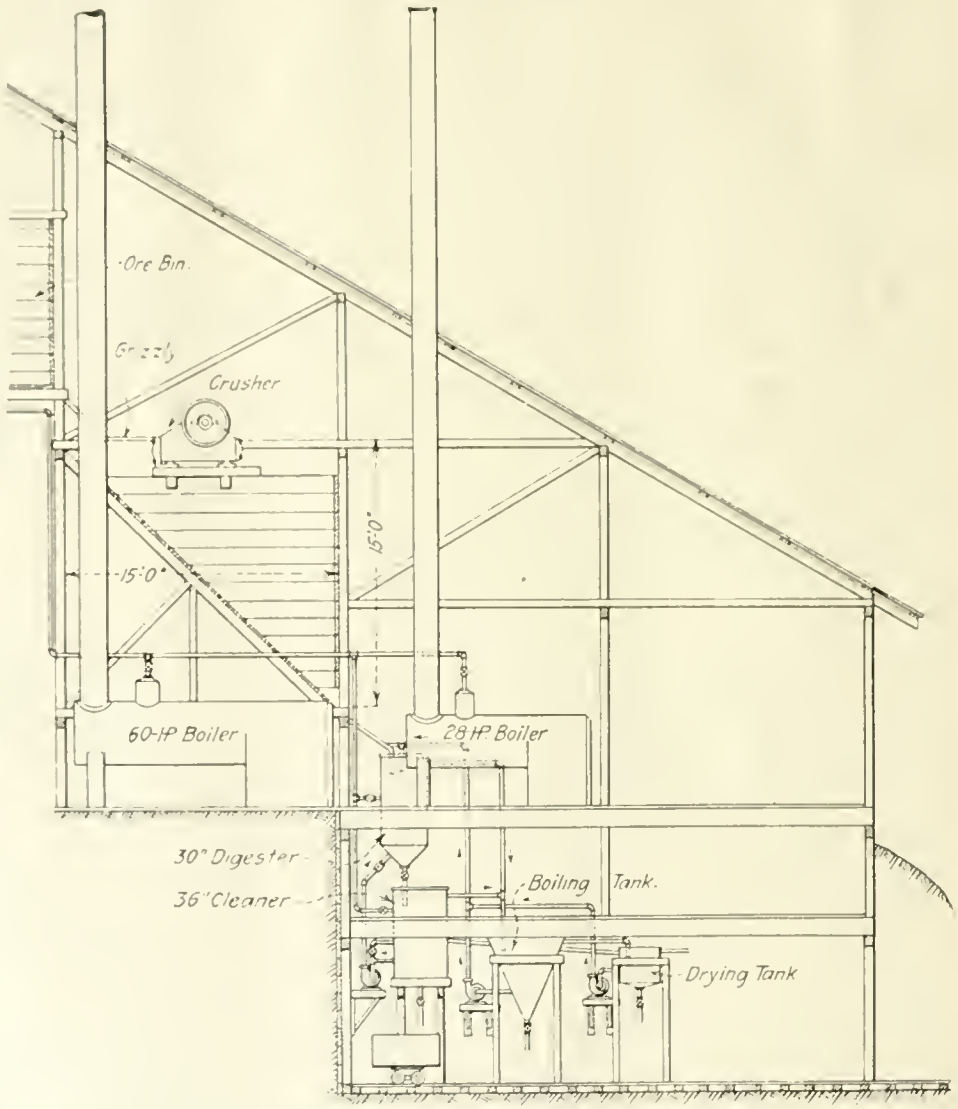


THE OZOKERITE BELT OF EASTERN UTAH.

The digester has a capacity of 800 lb. of ore plus sufficient hot water to fill the tank. The average time of treatment is 30 minutes. A preliminary separation will be made into impure wax and middling. The process will be practically continuous, molten impure wax being drawn off at the top of the digester to a steam-jacketed conical iron tank, 4½ ft. diam., set at a lower level, the middling dropping through a pipe with gate-valve to a cleaning-tank set directly underneath the digester. This tank is cylindrical with flat bottom, 3 ft. diam. and 4 ft. high. It is provided with a revolving plow driven by a

central shaft and is steam jacketed. The products of this tank will be three: molten wax at the top; silt and coarse rock at the bottom; and a mixture of these two with hot water in the middle section. Clean tailing will be made to discharge through a pipe and valve to a car operating in the tunnel beneath the mill. The wax from the top will join the wax from the digester in the conical cleaning tank. The middle layer will be drawn off by centrifugal pump and delivered to the digester near the bottom. The conical tank may be regarded as a concentrate-cleaner. Here the wax and hot water from the two preceding tanks will be subject to a further cleaning without agitation. Three products will result: a clean wax, a clean tailing, and a mixture of hot water, wax, and silt, which will be pumped back to the digester. The pure wax, with some hot water, will overflow to a shallow, round-bottom, open, steam-jacketed tank for the removal of entrained water, which will be pumped to the top of the digester, the last traces being finally removed by evaporation. The 'dry' wax will be molded for the market. This unit will have a capacity of 20 tons of ore per 24 hours. The extraction is nearly perfect. Provision has been made for the addition of other units when needed.

Steam is furnished to the jackets and the hoist by two locomotive-type boilers, with a total rated capacity of 100 hp. It will be noted that the water used for melting the wax is retained in closed circuit. Deficiencies due to evaporation will be balanced by supplying fresh water to the digester from the feed-water heater.



SECTION OF PROPOSED MILL FOR THE WASATCH OZOKERITE CO., UTAH.

The rate of flow through the apparatus is subject to easy regulation, and radiation losses have been reduced to a minimum, thus overcoming the two principal disabilities of the old process. As stated, this unit was assembled and thoroughly tested, so that the company has no doubt as to its satisfactory operation when installed at Soldier Summit. Incidentally this type of plant has been found suitable for other separations, involving leaching, or more properly, digestion, one suggested use being the extraction of potash from alunite.

PROPERTIES AND USES. After separation from the gangue, ozokerite may be treated with alkali and filtered through animal charcoal, Fuller's earth, or magnesium silicate. If sulphuric acid be used for purification there is a large loss of product. Peritz, in refining Boryslau ozokerite, secured 75 to 82% of crystallized paraffin (ceresin) and 9 to 18% of light oils. Inferior ozokerite may be distilled with superheated steam, yielding paraffin, lubricating oils, and naphtha. This paraffin should be distinguished from that obtained by filtration purification, to which the name 'ceresin' should be confined. Galician ozokerite yields, on distillation, 38% solid paraffin, 21% lubricating oil, and 25% petroleum. The paraffin may be dissolved by boiling in ether and purified on charcoal to a product containing 85.1% carbon and 14.57% hydrogen.[6]

The crude ozokerite is generally purified by one of the methods of filtration preceded by alkali treatment. The residue is distilled for paraffin, leaving a final residue of ozokerite pitch. At 150°C. a burning oil comes over. The fraction 200 to 300° consists of heavy oils and paraffin, which is worked for vaseline. The chief yield of paraffin is in the fraction 300 to 350°. The average yield at Boryslau has been given by Allen[1] as 6% of light oils up to 150°, 32% of heavy oils at 150 to 300°, 55% of paraffin.

[6]Beilstein & Weigand, Jour. Chem. Soc., Vol. XLIV, p. 1073.

Ceresin melts between 61 and 78°; it is odorless, colorless, has a waxy section, is hard but not brittle, and plastic without softness. It possesses the general properties of paraffin wax. Its specific gravity is lower than that of beeswax, from which it may be further distinguished by the absence of saponaceous matter. Ozokerite vaseline is produced by repeated filtrations of ozokerite through animal charcoal, followed by distillation for 3 to 4 hours with superheated steam at 250°. By this process 25 to 30% of vaseline is produced.

Ozokerite products are used for water-proofing, including waxed paper for packages; for dynamite cartridges, wrappers for soap, for lining barrels and kegs and acid-tanks; for wax candles, dolls, imitation-alabaster statuettes, decorations for confections; for liniments, salves, and plasters; for sealing jars; life-preservers, boot-blacking, varnish, shoemaker's wax; in electro-typing; for phonograph records, buttons, waterproof crayons, artificial honeycomb; as the base of many lubricating compounds, from axle-grease to gun-oil; and for pencils for writing on glass. The largest single uses are for insulating electric cables, as ozokerite pitch, and for manufacturing 'hard rubber,' such as that employed for telephone transmitters and receivers. Its increasing use is due to the ease with which the material may be manipulated, incorporated with resins, fats, and oils, by simple melting, or stained any desired color, together with the power of resisting acids. Much of the common beeswax is either pure ceresin or beeswax adulterated with it.

Before the War, there were 20 ceresin plants in operation in Germany and Austria, and none in the United States. The Austrian exports for the six years 1894-99, were 27,000,000 lb. of refined wax, and 57,000,000 lb. of crude. In 1898 the production was 17,100,836 lb. of which over 4,000,000 lb. was used in Austria. An estimate of the Austrian production from 1854 to 1910 is 662,500,000 lb. Imports into the United States in the decade from 1883 to 1892 amounted to 10,791,500 lb., ranging from a yearly importation of 565,000 to 1,870,000 lb. In 1908 imports totaled 3,595,393 lb. In 1910 nearly 8,000,000 lb. was imported and about the same amount in 1914. The total for the 5-year period, 1910-14, was 34,000,000 lb.[7]

The price of the Austrian product in the United States rose from 6 cents in the '90s to 15c. before the War. Since that time the price has soared to 45c. per lb., and it is reported that electro-typers have offered 75c. to $1 per lb. Prospects are bright for the development of the Utah district.

Phosphate rock sold in the United States in 1915 was 1,835,667 long tons, valued at $5,413,449. This is a decrease of 898,376 tons, due to exports to Germany being stopped. The output came, as usual, principally from Florida, Tennessee, and South Carolina; but there was a small output from Arkansas, Idaho, Utah, and Wyoming, according to the U. S. Geological Survey.

[7]Mineral Resources of the U. S. U. S. G. S. for various years.

Increase in Cost of Mine Supplies

Among the interesting information given in the report of the Hollinger Gold Mines, operating at Porcupine, Ontario, for 1915 is the following comparison of prices for supplies at the beginning of the War and at present:

Material and unit.	Price Aug. 1914	Price Mch. 1916	Advance. %
Mine Supplies			
Connecting wire, lb.	$0.50	$0.70	40
Dynamite (40%), cwt.	13.10	19.70	50
Dynamite (50%), cwt.	14.60	22.45	52½
Detonators, 1000	12.60	39.70	215
Fuse (safety), case	23.95	28.20	18
Fuse (time), 1000	5.40	10.25	90
Rails, ton	43.00	57.50	33
Shovels, doz.	7.60	9.00	18
Steel (drill), lb.	0.07	0.09	30
Steel (hollow), lb.	0.12	0.16	33
Track-spikes, keg	3.25	4.50	39
Track-bolts, keg	6.00	9.00	50
Mill Supplies			
Borax, lb.	$0.11¾	$0.17¼	47
Cyanide, lb.	0.15	0.16	7
Crucibles	0.07½	0.13	74
Cams, each	20.26	23.20	14½
Cam-shafts, each	83.00	90.00	8½
Lead acetate, cwt.	8.10	14.30	75
Liners (tube-mill), lb.	0.03¾	0.03½	8
Litharge, cwt.	5.65	12.60	127
Lead (pig), cwt.	5.65	10.06	78
Muriatic acid, cwt.	1.70	2.93	80
Pebbles (Danish), ton	22.03	26.80	22
Shoes and dies, cwt.	4.85	6.55	37
Zinc-dust, lb.	0.06⅝	0.27	427
Zinc, spelter, cwt.	6.48	17.25	276
General			
Machinery and parts			10 to 40
Electrical equipment			20 to 50
Corrugated iron			50
Iron and soft steel			50
Tool-steel			500
Pipe			60
Nails			40
Lubricating oils			10
Fuel-oil			51
Gasoline			65

Japan's foreign trade, particularly in the export of copper and war munitions to Russia, has been stated recently to have increased tremendously, yet the official figures show but little increment in the total of the country's foreign trade for 1915. Exports from Japan last year were but $58,000,000 greater than for 1914. The total was $304,000,000, of which only 11% went to Asiatic Russia; the United States took a much larger proportion, 29%, and China took 20%, Great Britain and India taking 16% between them. Of Japan's imports, a total of $266,000,000, the United States supplied 20%, India 28%, China 16%, and Australia 15%. It is evident that the United States and Japan are good customers of each other; also that the British possessions and China have an important trade with Japan.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Potash occurs in the leucite of the lava of the Leucite hills of Sweetwater county, Wyoming; but its commercial extraction has not yet been proved feasible.

Copper in some of the silver ore (1170-ft. level) at the Tonopah Extension mine caused an increase of cyanide consumption in the last financial year of the company.

Since 1880, when mining first commenced in Alaska, the Territory has produced gold, silver, copper, tin and other minerals to the value of $300,953,751. This great mineral region was acquired by the United States in 1867 for $7,200,000, on the advice of William Seward.

Explosives in Rand mines are often carried in fibre bags, which are inflammable. Experiments show that when the canvas is immersed in saturated solutions of sodium tungstate, ammonium phosphate, or sodium silicate, dried, and tested, they are not liable to catch fire.

Wire ropes should be lubricated carefully, not hastily. The lubricant should penetrate to the hemp centre and should coat thoroughly the inside wires. Cables can be lubricated while running, if their speed at the time is not too great. They are passed through a trough containing lubricant, being pressed under the oil by hand or by passing beneath a small sheave arranged for the purpose.

Salts containing precious metals continue to rise to the surface of tailing-dumps at Tonopah, Nevada. During the year ended February 29, 1916, 1018 tons of 'sweepings' were recovered by lessees from the Belmont ponds. This material assayed 0.343 oz. of gold and 55.92 oz. of silver per ton, and was worth $34,328. Smelter charges on this fine stuff are exorbitant, and a plant to treat it locally is to be erected.

In testing a part of the Mother Lode in Calaveras county, recently, over a length of 6000 ft., it was found that 5600 ft. of trenching had to be done, excavating 43,000 cu. ft. of rock; 1502 samples being taken and assayed, the whole operation costing $4500. The loose dirt was first removed and then fresh rock was blasted. The trenches were 22 ft. apart when in ore, and averaged 84 ft. apart over the entire distance.

Advocates of crushing gold ore in cyanide solution years ago made a great point of the saving of cyanide effected; but according to T. B. Stevens, in a communication to the C. M. & M. Society of South Africa, his experience does not confirm this. Apart from the dissolving of the gold he found that in order to obtain good precipitation on the zinc a much higher cyanide strength is required, than when the solutions are frequently renewed by dilution, as when crushing in water; in fact he visited many plants where a high cyanide strength has been in use solely for the purpose of obtaining good precipitation.

Advance in the price of silver makes the intrinsic value of silver coins a matter of interest, for, if the intrinsic exceeds the nominal value, there is always a strong possibility of coins being melted into bullion, and the refined contents being placed on the market. The Mexican silver dollar is already worth more dead than alive. Legally it is supposed to circulate as 50 cents U. S. Its intrinsic value as unrefined bullion in May was about 54c. Had not Mexico been already denuded of silver dollars owing to internal strife, the Government would have found it difficult to retain these silver dollars as currency. Should the price of silver exceed 90c. it would begin to be worth while to ship to Europe and there refine the Indian rupee, and at 92c., the Straits' dollar. The amount of Straits' dollars affected is about 12,500,000. In March 1907 the weight of this dollar was reduced from 416 to 312 grains, owing to the rise in the price of silver. An advance in the price of silver to 90c. would create a serious problem for the British authorities. Considering the size of the stock of rupees it would be impossible to recall and re-mint the metal quickly into a coin with less silver-content.

Degrees Baumé, a term which is in common use among acid and petroleum operators, refiners, and manufacturers, is likely to be confusing to those who are not acquainted with the method by which the system of units was established. For liquids lighter than water, among which are mineral oil and acids, the Baumé measurements are opposite to those of specific gravity. That is to say, the greater the specific gravity of the liquor, the lower the Baumé measurement, and vice versa. The use of the Baumé scale of gravities for liquids has given considerable annoyance as well as convenience in certain industries, especially oil. A natural and common mistake due to the use of Baumé scale is in the mixing of different gravities of oil to obtain a product of certain gravity on the assumption that the Baumé scale is a direct measure of specific gravity. The Bureau of Standards has adopted the following relation between specific gravity and degrees Baumé, for liquids lighter than water:

$$\text{Degree Baumé} = \frac{140}{\text{Specific gravity at } \frac{60^\circ}{60^\circ} \text{ F.}} - 130, \text{ or}$$

$$\text{Specific gravity at } \frac{60^\circ}{60^\circ} \text{ F.} = \frac{140}{130 + \text{degrees Baume}}$$

Some Baumé and specific gravity equivalents, as given in Redwood's 'Treatise on Petroleum,' are as follows: 10B. = sp. gr. of 1, or water; 20B. = sp. gr. of 0.9333; 30B. = sp. gr. of 0.875; 50B. = sp. gr. of 0.7778; 60B. (gasoline) = sp. gr. of 0.7368; and 90B. = sp. gr. of 0.6364. A table for acids, heavier than water, should be found in any good chemistry text-book.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

Zinc, Lead, and Pyrite Markets and Prices in May.

Abnormal prices for zinc ore were reduced to lower standards during May. The base range for top grades at the beginning of the month stood at $100 to $110 per ton, premium grades selling at the latter; second grades ruled strong and in good demand, on 52% zinc-content; low grades were eagerly sought by the refineries operating in the field. All producers were thus satisfied, and no surplus ore was found at any point in the field. About the middle of the month prices sagged appreciably, and lower-grade products experienced a noticeable indifference on the part of buyers, which increased toward the close of the month, to the point where such ore was not sought at all, and operators not connected with refineries were left out entirely, with the result that from 4000 to 5000 tons of concentrate was left in bins unsold. The base price had dropped to $80 per ton for top grades down to $75 per ton base for medium grades, assaying down to 52% zinc-content. Production of mine-run ore continued unabated, regardless of the steadily declining markets, and shipments compared favorably with periods of high prices. A score of new producers came into operating existence at as many different points in the field. Splendid weather and road conditions fostered operations in all branches. Mill building received an impetus on a scale unknown before. Contracts were closed for new plants in every centre of the field. A careful enquiry revealed 57 drilling-machines on exploration work in virgin and old ground.

Lead ore continued in good demand, the month opening at $100 per ton for 80% product, declining until the close of the month to $88 and $93. There was little surplus ore in the field at the close of the month.

Producers of pyrite experienced a dull month in spite of commercial sulphuric acid being high. A heavy surplus was carried over.

Zinc carbonate producers, mostly in the northern districts of the field, sold a small quantity of ore in open market, the product going to the Eagle-Picher Lead Co., a recent amalgamation of large corporations. While quotations ranged from $55 to $70 per ton, sales were reported at $40 to $45 for choice ore. Production showed appreciable gains, good weather affording the incentive to miners to rig-up open-air washplaces, as this class of zinc ore cannot be cleaned advantageously during severe winter weather.

Deliveries of ore totaled 40,714,000 lb. of zinc, 944,110 lb. of lead, and 7,427,300 lb. of pyrite. The gross turn-in of raw concentrates for the month from mines aggregated 16,000 tons; net deliveries to smelters 11,600 tons. Sales were distributed among 15 buying concerns, 20,357 tons in all. The New Jersey Zinc Co. secured 28% of this. The Granby Mining & Smelting Co., although not represented on the ground, was much the heaviest buyer of high-grade refinery ores. The present situation in the field warrants the extension of separating-plants. The Benton district lead with 9360 tons of blende, followed by Galena with 2496, Mifflin with 2306, Cuba with 2229, Hazel Green with 1543, Linden with 1000, and Platteville with 774 tons. Cuba supplied 1522 tons of pyrite also.

Good results are reported from the Wisconsin Mining School at Platteville, of which R. Davis is director. The class of 1916 was the largest since its opening.

TORONTO, ONTARIO

Hollinger-Acme-Millerton Merger.—McIntyre and Other Porcupine Developments.—Gold at Beattie.—Ottawa Mint to be Enlarged.

The merger of the Hollinger, Acme, Millerton, and other properties at Porcupine into the Hollinger Consolidated Gold Mines, Ltd., with a capital of $25,000,000, was formally ratified by shareholders of the companies concerned at Montreal on May 15. The general manager, P. A. Robbins, was added to the directorate. The enlargement of the mill as foreshadowed in the manager's report on the consolidation will be proceeded with at once. The company has increased the wages of surface-men 25c. per day, and has revised its loyal service bonus system so as to give employees a higher percentage on their wages.——The position of the McIntyre has been greatly improved by recent rich discoveries at 700 and 1000 ft. depth. The vein on the 700-ft. level is 62 ft. wide, valued at $14 per ton, and has been extended 140 ft. each way. On the 1000-ft. level the orebody is 25 ft. wide, valued at $15.30 per ton. Ore reserves as of March 31, not including later developments, were estimated at 210,000 tons valued at $2,247,000. The total bullion production of the year was $779,990 and disbursements $447,946.——The Hollinger Reserve has been sold to Bernard McEnaney, and diamond-drilling will be undertaken to determine its value at depth.——The Davidson, after being in litigation for some years, has been acquired by a Western syndicate, which is unwatering it.——The Schumacher mill is treating 150 tons daily. The company is now extracting ore from the 600-ft. level. Gold valued at $23,000 was shipped in April.——The West Dome Consolidated is obtaining good results from diamond-drilling. A vein cut at 513 ft. shows 5 ft. of ore assaying $45.——At the Success, No. 1 vein at the 20-ft. level has widened to 18 in. and assays well.

An important discovery of gold has been made in Beattie township, northern Ontario, about 3 miles from the Croesus mine. The vein is from 8 to 18 in. wide. Rich samples have been taken. C. A. Foster, of Haileybury, has acquired a controlling interest.

The Croesus in Munro township is producing at the rate of about $1000 per day. The gold is free and easily recovered.

The Canadian government will enlarge the mint at Ottawa to meet the great demand for gold caused by the War. A new temporary building will be erected immediately adjoining the present permanent structure and the output of gold coinage considerably increased.

Metal outputs of the Province in the first quarter of 1916 are as follows: gold, 76,307 oz.; silver, 5,200,167 oz.; copper, 3644 tons; nickel, 6680 tons; pig-iron, 94,678 tons; cobalt, 450 lb. There were increases in all, gold being 31,511 oz. more. The total value was $14,276,382, against $9,358,210 in this period of 1915.

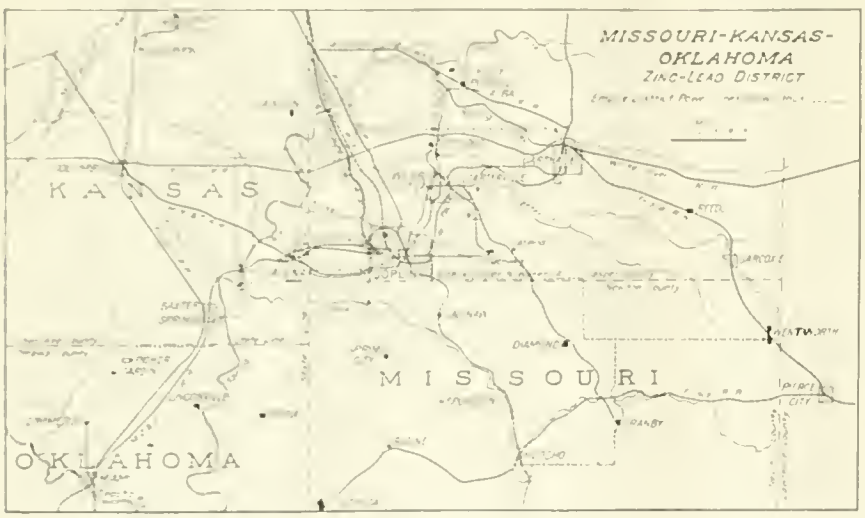
At Cobalt there are 2700 men employed, about half underground. Silver is higher than at any time in the life of the district. On account of general mining activity and considerable recruiting for the army there is a scarcity of labor through northern Ontario. The Union does not consider the recent wage increase sufficient.

On June 17 the Hollinger company pays $120,000, making $4,890,600 in 4½ years.

JOPLIN, MISSOURI

1500-ton Mill at Webb City; Plant of Similar Capacity at Picher, Oklahoma.—Drilling Campaign.—Notes.

With a capacity of 1500 tons of ore per 24 hours, the No. 2 mill of the D. C. & E. Mining Co., on a 30-acre lease of the Carter land, north of Webb City, Missouri, will equal in size the mills of the Media, and the Star company's, north of Webb City, and the Granby company's Klondike mill at Granby, Missouri. The new plant is ready for operation. It is situated on a shaft started a number of years ago by Chapman and Lennan, and completed by the present company, of which J. J. McLellan is general manager. To the south-east from the mill, situated on much higher ground, is the old shaft of the Bird Dog Mining Co., to which a tramway, 75 ft. high has been constructed. This shaft is 650 ft. from the mill. The tramway is the highest in the district. North-east of the mill is the old Blue Bell shaft, 400 ft. away, to which a tramway has been built. At the mill shaft and at the Blue Bell shaft mining is done in sheet-ore at a depth of 134 ft., continuing down to 160 ft.; but at the Bird Dog shaft, due to the greater surface elevation, the formation is found deeper. Part of the ore feed



to the rougher-jig comes direct from the crusher, thus eliminating the necessity of handling a large tonnage of 'dirt' over the rolls. Any ore that passes through ½-in. mesh goes direct to the rougher. A Corliss steam-engine plant has been installed to drive the mill, the equipment of which is to consist of two rougher-jigs, one cleaner, and one sand-jig. The cleaner has seven 36 by 48-in. cells, and is the largest in the Joplin district. The concrete settling-tank, 40 ft. wide by 50 ft. long and 10 ft. deep at the deepest point, is likewise the largest tank in the district. Ten sludge-tables are housed in a separate building, a short distance north-west of the mill. The tract that is to be mined is now thoroughly drained, for the first time in six years, as this section of the district has been inactive since the shutting-down of the big Yellow Dog property. The operators say they will recover 4% of blende and lead.

Almost duplicating in general features the plan of the D. C. & E. plant, north of Webb City, is the new 1500-ton mill of the Picher Lead Co. at Picher, Oklahoma, the fourth plant to be constructed by this company in a field that only recently has been developed. In the matter of jig-feed, sludge will be taken off by dewatering screens immediately after the crushed ore leaves the crusher, and before it reaches the rolls, undersize from a ½-in. screen passing directly to the rougher in as dry a form as possible where it is distributed. Oversize goes to rolls, and is again screened and dewatered before going to the rougher. The three mills now in operation by the Picher company are producing heavily. Ore is mined at a general depth of 250 to 300 ft. The plants now at work have a capacity of 350 tons each per shift, or about 1000 tons per day. These mills make the district generally very busy.

North of Picher, a number of prospecting drills are at work. Lucius Buchanan has 12 drills on a 40-acre lease of the Toskoff land lying along the State line in Kansas. The good strikes made by the Picher company on the south, and by the Commerce Mining & Royalty Co. on the north, have encouraged Buchanan, who intends to devote at least six months to his prospecting campaign, regardless of whether he finds ore or not. On the Cooper land, near to the Toskoff property, a big drilling campaign has been launched by G. Hayless and Will and Joe Walker, who have more than 100 acres under lease. In the first hole put down 'shines' of zinc-blende and galena were found from 220 to 240 feet.

Sheet-ground mining is to be started on the Continental ground, in west Joplin, by the C. M. & H. Mining Co., now operating the Glendale mine, where all the work in the past has been in an upper formation, beyond the sinking of a shaft to the the sheet-ore which occurs at a depth of 200 ft. The disseminated ore, heretofore worked, is found at 140 ft. In working the deeper ground, tests show that a recovery of about 2½% may be expected.

The Wade Mining Co., of which Evans W. Buskett is the Joplin manager, while John L. Fay, C. E. Brenton, and Frank W. Bane, of St. Louis, are the operators, has taken a lease on 120 acres of the Wade land, 15 miles south-east of Joplin, in a district that has not been mined for eight years. The Gilt Edge Mining Co. operated a mill at that point, but later removed its plant. A sub-leasing company will construct a tailing-plant on the Gilt Edge dump, while the Wade company has purchased the Emperor mill, from a west Joplin company, and will move it to its new mine which has now been quite extensively developed. Ore is opened in two shafts at a depth of 40 to 80 ft. in soft ground, and will yield 5 to 15% blende.

As an indication of the increased operations in the Joplin district, the figures of power output of the Empire District Electric Co. during a recent week are of interest. The demand was 2,936,870 kilowatt-hours, with a peak load of 28,700 kw., compared with 1,588,680 kw.-hr. and 16,700 kw. a year ago. In the third week of April 587 hp. was contracted for, over five times the amount of that week in 1915.

Owing to the lower prices of ore, wages are to be reduced in this district and the 'hoister-men' at several mines have 'quit.' They were paid $4.75 per shift, but a cut of 50c. was to be made. Their union of 400 members is the strongest. Some shovelers also have 'downed tools.'

The output of the Missouri-Kansas-Oklahoma region last week was 5827 tons blende, 70 tons of calamine, and 844 tons lead, averaging $73, $54, and $83 per ton, respectively. The total value was $501,717, and for 22 weeks, $18,214,975.

A 400-ton mill was erected for the Milton company, between Webb City and Carterville, in 31 days. This is claimed to be a record in construction.

A suit has been started at Miami by Mrs. M. N. Warner, a Quapaw Indian, and her husband, against the Commerce Mining & Royalty Co. and others for $200,000, already collected by the defendants as royalties on lands which they allege were secured by the defendants from them by fraud, also further damages amounting to $300,000. The land was sold by Mrs. Warner for $8500, without her knowing that it contained zinc and lead ore. Production so far is $800,000, on which defendants received $200,000 in royalties, and $1,000,000 of ore still remains.

In 62 holes drilled near Cardin only three revealed no ore.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Since 1898 the U. S. Geological Survey has been systematically investigating the Territory, yet much remains to be done. Alfred H. Brooks is in charge, with (this season) T. Chapin at Ketchikan, G. H. Canfield in the south-east (water resources), D. C. Witherspoon, A. C. Spencer, and H. M. Eakin at Juneau, J. W. Bagley, and B. L. Johnson in Prince William Sound, F. H. Moffit in the lower Copper River region, G. C. Martin, A. G. Maddren, and R. M. Overbeck in the Neanana coal-field, S. R. Capps and C. E. Griffin in the Kantishna district, J. B. Mertie at Tolovana, and R. H. Sargent with G. L. Harrington on the lower Yukon river.

Juneau

During May the Alaska Gastineau produced 175,215 tons of ore averaging $1.40 per ton, against 165,930 tons at 94 cents in April. The recovery was 82.85%. Conditions underground continue to improve.

The Treadwell group reports will be reviewed next week.

The Lituya Gold Mining & Dredging Co. has been incorporated with a capital of $400,000 by H. H. Williams of Juneau and F. P. Cook of Spokane, to develop property on Lituya bay. Prospecting by drill is to be done this summer, to be followed by a dredge if satisfactory.

ARIZONA

Cochise County

Recent happenings in the Bowie district, in which is the Dos Cabezas range, are attracting attention to its possibilities. There are included four mining areas, namely, the Apache Pass, 10 to 14 miles south; Happy Camp, 9 miles south; Buckeye Canyon, 8 miles west; and Gold Gulch, 12 to 16 miles west of Bowie. The north slope of the range is well mineralized, with gold, silver, copper, and lead. In Apache Pass the old Quillian is the most important property, yielding silver-lead ore. Happy Camp has two good copper mines. In Buckeye canyon the Bowie Mines Development Co. is to build a 50-ton mill to treat silver-lead-gold-copper ore. Gold Gulch has promising ground. J. H. Jaque, publisher of the *Bowie Enterprise*, is taking an active interest in the development of the district.

Gila County

The Inspiration treated 470,000 tons of ore during May, equal to 5,640,000 tons per year. The new sampling mill is almost complete. Foundations for a duplicate motor-generator set are ready for the machinery. This is for the main shaft hoists.

At the Old Dominion mill changes include installation of Senn vanners and Allen cones. The plant treats 800 tons daily. Foundations for new power machinery are being poured. Two Sterling boilers will be erected. The mine flow of water is 6,500,000 gal. per day, a decrease. The May output was 3,500,000 lb. of copper.

From the Gibson mine at Globe the company and lessees are shipping up to 400 tons of ore monthly to the International smelter at Miami. In April the total was 460 tons. The ore is chalcopyrite, much containing 20 to 35% copper. Development at 1400 ft. in the Arizona Commercial, the deepest work at Globe, is good. The monthly output of copper from No. 10, 12, 13, and 14 levels is 500,000 lb., with earnings over $70,000.

Mohave County

Forty-six miles east of St. Thomas in Nevada is the Grand Gulch copper mine, producing 80 to 100 tons of ore per week. On June 1 there was paid 3c. a share. Ore shipped contains 12 to 16% metal. A dump of 15,000 tons assays 5%; this is being graded up to 12%. The haul to the railroad is 45 miles; 75 men are employed.

A wide body of milling ore has been cut at 1400 ft. in the Tom Reed mine.

Santa Cruz County

The Chamber of Commerce of Nogales is awakening to the importance of the mining industry of this county, says a report of the Arizona State Bureau of Mines. Recently a meeting of that body was held, the object of which was to discuss the erection of a custom mill, with an arrangement for having facilities for treating tungsten ore. Many other parts of the State have need in this line.

CALIFORNIA

Amador County

On June 5 the syndicate that acquired the old Eureka mine recently made the first payment of $41,000, being one-fifth of the purchase price, on the Wildman-Mahoney-Lincoln claims owned by the Lincoln Consolidated Co., which owns 4000 ft. on the strike of the Mother Lode on the northern side of Sutter creek. It is also reported that another syndicate of Seattle operators has taken an option on the ground extending from the Golden Eagle to the Keystone, including therefore the South Keystone and South Spring Hill properties.

Eldorado County

The new shoot at 800 ft. in the Montezuma mine at Nashville shows 7 ft. worth $20 per ton.——The Orum mine near this place has been acquired by W. W. Hurt and others.

San Bernardino County

(Special Correspondence.)—The 'spud-diggers' in the Atolia district are pleased that the Federal government has several

HAND-JIGGING TUNGSTEN ORE AT ATOLIA.

investigators in the field who are looking over the granite formations that show tungsten possibilities, because, in case of the taking up or withdrawal of such lands the Government

may develop them by leasing. Storekeepers are displaying such signs as 'cash for high-grade,' 'meal tickets for high-grade,' or 'groceries for high-grade.' Buyers of outside production of ore are again on the ground, and it is not uncommon to see two or three shipments by automobiles to Los Angeles, where it is sampled and sold on a basis of $1 to $1.25 per pound. Several tons have been picked up this week at prices varying from $45 to $50 per unit. Shippers of the product contend that not a pound of this output is going to the Schwab interests, or those agents representing the Bethlehem Steel Company.

Atolia, June 7.

The new mining camp of Goldstone, 33 miles north-east of Barstow, a few miles south of Randsburg and Atolia, at an elevation of 3000 ft., is beginning to attract attention. It is 8 hours by auto from Los Angeles, costing $10 the round trip. Three recent discoveries, the Red-Bridg, Goldstone, and Lucky Find, are working in high-grade ore. The district is yet in shallow depths, now about 50 ft. Free gold continues to this depth. On the Red-Bridg the ore has been stripped about 200 ft. on the surface, all of which pans free gold. The formation here is schist, shale, and quartzite, with igneous rocks of different character in the nature of dikes and flows. The rich gold seems to be found near the contact of the igneous rock with the sedimentary rocks, and favors the schist.

Humboldt County

(Special Correspondence.)—Wilbur H. Grant, of San Francisco, is making an examination of the Horse Mountain Copper Co.'s ground. The company desires to start a diamond-drill proving ore, with a view to offering the property for sale. Later on the company will have a mineral survey made from which will be excluded those of its 74 locations reported on adversely by Mr. Grant. By the end of this week O. H. Hershey will also examine the same ground, but independently, in the employ of Charles Willis Ward, of Long Island, New York, and Eureka, one of the largest shareholders. Mr. Hershey will also lay out further work for the drill at the Humboldt Copper Co.'s property, where an immense body of low-grade ore was discovered through his advice last year. Mr. Hershey will go to Prospect hill near Orleans Bar, where some promising gold-bearing veins have been found, and will examine 27 claims located for Mr. Ward there.

The Corona Mining Co., which operates a gold placer at Hawkins Bar, just over the Trinity County line, and owned by Eureka people, yesterday shipped its third bar from three part clean-ups this season. The bars averaged $1000 each. It is estimated that the mine will have water for four or five weeks yet. The riffle sand, composed mostly of pyrite, is rich in platinum metals, about an ounce of coarse metal being recovered to each 50 oz. gold amalgamated.

Eureka, June 7.

Shasta County

For reasons unknown at Ingot, the American Metal Co., which had an option on the Afterthought copper mine, has paid-off all hands, numbering 35. The vein is said to be small and the grade low.

Sierra County

Hydraulicking is soon to commence at the old Bunker Hill-Herkimer mine, 12 miles from Downieville. Some rich gravel was uncovered in January. G. De Brettville, of San Francisco, controls the property.

Tuolumne County

(Special Correspondence.)—Work was begun this week at the Tarantula mine, recently acquired by Henry T. Gage. It is understood that S. B. Thompson of New York, and others have become associated with Mr. Gage in his properties. It was expected that at least 40 men would be on the pay-roll by the end of the week. The Tarantula and the other holdings of Mr. Gage and his associates are situated in the vicinity of the well-known Shawmut.

Consignments of machinery for the Rawhide frequently arrive. In a carload received this week was a pump of large capacity, which will be installed on one of the stations in the mine. The work of unwatering has been in progress for many weeks.

A shoot of rich ore has been uncovered in the Chilano mine, near Tuttletown. The orebody is several feet wide, a streak of it being thickly speckled with gold.

Sonora, May 26.

COLORADO

Boulder County

The Wolf Tongue Mining & Milling Co. at Boulder is being sued by D. and O. Hinman, who are lessees on the company's property. They allege that they delivered 13 lots of tungsten ore at the company's mill between October 12 and December 31 last. They demand $8925.84; the Wolf Tongue offers $3209.19. At the then market prices, ranging from $15 to $45 per unit, plaintiffs declare the ore was worth the amount for which the suit is brought. The defendant offered to make settlement on the basis of a $15 schedule.——Fourteen lessees besides the Hinman brothers are interested in the outcome of the suit, as they hold similar contracts with the company. If the suit is determined in favor of the Hinmans, it is understood the other lessees will demand payment for the tungsten they delivered on the basis of the market prices, which are from 100 to 150% above the Wolf Tongue schedule.

Judge Neil F. Graham has since ruled that contracts held by lessees of tungsten lands of the Wolf Tongue company should be interpreted to require payment of market prices for ore produced by the lessees.

Clear Creek County

(Special Correspondence.)—The members of the Colorado Central Leasing Co. were incorporated as a company in Denver on May 24. The plans of the company are now fully decided on, and sufficient capital has been subscribed to complete the work of sampling and re-opening the property, which will take 6 to 8 weeks. A preliminary testing plant is to be erected at the mine to determine what treatment the ore requires. Money has also been subscribed to erect a tramway a distance of two miles from the mine to Georgetown, and for the building of a mill with a daily capacity of 100 tons. Tallmadge Kyner, the manager, states that all tests made so far are beyond expectations.

J. C. Hershey, manager of the Red Oak company, expects to re-build the aerial tram from the mine to the foot of the mountain.

A recent examination made of the Bard Creek Mining Co.'s mill resulted in a decision to install almost entirely new machinery.

A new campaign is to be instituted by three mining companies here, now that the supervision of their properties has been placed in the hands of Fred B. Hitchings. Machinery will most probably be installed on each mine for driving.

The Mid Colorado company is to re-model its 50-ton mill, using a ball-mill for re-grinding, and flotation. The present aerial tram is to be extended 1000 to 1200 feet.

Georgetown, May 24.

Ouray County

During April the Camp Bird's profit from 1389 tons treated was $26,000.

San Juan County

Under prevailing conditions this county offers a good field for prospectors in gold, silver, lead, zinc, and tungsten. Flotation treatment has greatly stimulated production.

The Silverton district shipped 138 cars of ore and concentrate during May. The principal producers were the Sunnyside, S. D. & G., Gold King, and Iowa-Tiger.

San Miguel County

On June 1 employees (1000) of the Tomboy, Liberty Bell, Smuggler-Union, Colorado-Superior (Black Bear), Primos Chemical, Wagner Development, and Humboldt companies were granted a bonus of 30c. per shift, provided silver remains at 65c. or over per ounce, and each employee works the full month.

IDAHO

Blaine County

The Wilbert Mining Co., operating near Arco, reports as follows for the year ended May 1, 1916:

The high price of lead allowed of a good deal of poor ore being extracted, also small streaks and shoots that would not pay otherwise. From No. 5 level to the surface the main shoot is nearly all stoped. The mill treated 15,204 tons, assaying 25% lead and 3.86 oz. silver. Concentrate produced was 5787 tons, averaging 52.06% and 8.02 oz., equal to 6,025,600 lb. lead and 46,419 oz. silver. The cost was $3.56 per ton. The revenue from all sources was $223,382. Dividends absorbed $30,000. Cash in banks amounts to $42,468.

The A. S. & R. Co., controlling the Federal company in the Coeur d'Alene, has taken over the North Star-Triumph lead-silver-zinc claims near Hailey. E. P. Smith is in charge. The property contains a good deal of ore, but it is rendered complex by the admixture of arsenical pyrite.

Idaho County

In the Buffalo Hump, Ten-Mile, and other parts of this county, contiguous to Grangeville, are complex sulphide ores resisting ordinary treatment methods; but recent investigations show that flotation will give a good recovery, according to E. M. Griffith of Grangeville.

Shoshone County (Coeur d'Alene)

Dividends paid in May totaled $722,175 as follows: Bunker Hill & Sullivan, $163,500; Caledonia, $78,150; Hecla, $100,000; Hercules, $300,000; Success, $45,000; and Tamarack & Custer, $35,525. June payments are as follows: Bunker Hill & Sullivan, $163,500; Caledonia, $78,150; Federal, $120,000; Hecla, $150,000; Hercules, $300,000; Interstate-Callahan, $697,485; and Success, $45,000; a total of $1,554,135.

The Pine Creek district is being examined by J. B. Umpleby and E. L. Jones of the U. S. Geological Survey.

A final inspection of the Nabob, Sidney, and Little Pittsburg mines in the Pine Creek district is being made by engineers of the Anaconda company, which recently acquired the Douglas near-by.

The contract with the A. S. & R. Co. having expired, the Tamarack & Custer company, which operates lead-silver mines in the Nine-Mile district has closed-down its properties temporarily, pending diversion of the output to the Northport smelter in Washington.

In order that it may purchase more property the Stewart Mining Co. is to increase its capital from $1,250,000 to $3,000,000.

MICHIGAN

The Copper Country

G. M. Hyams, of Boston, a shareholder (1300 shares) in the Tamarack company, whose mine was recently sold to the Calumet & Hecla for $59 per share, has brought suit to restrain the sale. The C. & H. held 19,400 shares of Tamarack, which makes the former both vendor and purchaser, the sale being made void under the statutes. The price offered is also considered too low. In view of this suit the Tamarack company has asked the C. & H. to defer transfer of the property beyond July 1, the date that this was to take place. The C. & H. directors are considering the proposal.

The old Carp Lake mine, bordering on Lake Superior, and 22 miles west from Ontonagon, is to be re-opened under control of R. T. Looney. Work was stopped in 1863, after the 16-stamp Cornish-design mill was burned. Copper was sent to Detroit before the Calumet & Hecla was discovered. Ore occurs in rich lenses in sandstone. Development can be done by adits. Examinations made show the ore to carry from 44 to 53 lb. of copper per ton.

MONTANA

Granite County

At the old Brooklyn mine near Maxville 6 ft. of good copper-silver ore has been opened at a depth of 280 ft. A 100-ton mill is about ready to commence ore treatment. Spokane people are in charge.

Silverbow County

At the Butte & Zenith, south-west of Butte, the shaft is down 765 ft., 95 ft. being sunk and timbered during May in spite of 300 gal. of water per minute. Another 300 ft. is to be sunk. The vein is of better grade at depth.

At the Butte-Main Range the Tuolumne company has commenced work. The Colusa-Leonard mine, which is to be developed by the Tuolumne, will commence shaft-sinking from 1628 to 1628 ft. depth.

Sinking is finished at the Butte & London. Prospects are good.

The fire in the Pennsylvania mine of the Anaconda that killed 21 men some months ago is out and production is now 750 tons daily.

During May the Butte & Superior produced 16,150,000 lb. of zinc in concentrate, from 54,100 tons of ore. Silver amounted to 310,000 oz., and 250,000 lb. of lead. At 1100 ft. east and west of Jersey Blue shaft good orebodies have been developed.

NEVADA

An indication of the increase in mining operations in this State is shown by premiums paid by mines to the State insurance fund as follows:

January	$17,245	$12,002	$18,341
February	20,553	11,765	17,195
March	21,250	12,695	16,558
April	22,143	13,312	18,736

The income in April of this year was the largest recorded. Mining contributes 80% of the total fund. Since July 1, 1913, the revenue totaled $681,188, and amounts paid $547,572.

Clark County

Goodsprings now boasts a daily paper called the *Goodsprings Gazette*, showing that the zinc district is advancing in importance.

Esmeralda County

(Special Correspondence.)—The Nevada New Mines Co. has purchased the Black Eagle mine and mill. The plant has a daily capacity of 75 tons. Water, piped from a near-by hill, flows to it by gravity. The company will operate both its mills, and press underground work with increased energy. Ore reserves in the main mine are reported as satisfactory.

Rawhide, June 4.

Lincoln County

Two dividends of 2½c. a share each have been declared by the Prince Consolidated of Pioche. May shipments were 13,200 tons of ore.

Lyon County

Interest in the copper and gold and silver properties in the Yerrington district is increasing. A large number of prospects have excellent futures. Some of the best mines are the Western Nevada, McConnell, Malachite, Yerington Consolidated, Utah-Yerington, Butte-Yerington, Mason Valley, Bluestone, Empire-Nevada, Montana-Yerington, Reno-Yerington.

Mineral County

(Special Correspondence.)—At the Luning Idaho mine the road is completed, and a truck can negotiate the hill easily to the mouth of the Hahn adit. The McDavitt shaft is down 100 ft. on the foot wall. The Conte winze is down 25 ft., showing bunches of high-grade ore, both carbonate and sulphide. Indications are good for entering the solid body of ore at no great depth.

The Meyer adit of the R. B. Todd Mining Co. is in 314 ft., with a cross-cut running south of the adit where some ore has been encountered. There are indications that the vein soon will be cut.

There were 11 carloads of ore being unloaded at Luning at the end of May. Shipments are being made from the following mines: Mayflower, Never Sweat, Turk and Wall Street, and Silver Guardian. This property is being worked by lessees and belongs to F. M. Smith. Lessees are also working on the Vacation, and regular shipments are being made from the Champion, Anderson, Wedge Copper, Hartwick, Houghton, and Luning Aviator. There are 12 lessees working and shipping from the Copper Queen, as well as on the Finney, Shipper, and others. There are 300 men working in the district at mining, teaming, etc. There are three boarding-houses at Luning. There are two boarding-houses in New York canyon. The town also supports three saloons, and two others are contemplated. Three stores supply the camps and there is talk of others. Mr. Beatty of Mina extended the telephone line to Luning *via* New York canyon and Champion; a great convenience. Car-loads of lumber are coming in, and carpenters are busy erecting buildings at Luning as well as at surrounding camps.

The leaching plant at Ludwig is working successfully. There are over 200 men employed there. The Nevada-Douglas has recently cut a large body of high-grade ore which it is shipping. The company expects to be able to receive custom ore at the leaching-plant early next month.

Luning, May 31.

NEW MEXICO

San Miguel County

Near Ribera, in the Pintada canyon, on the Santa Fe railroad, the C. H. Thaggerd Copper Co. is erecting a 100-ton leaching plant. The vein is of good width and will average 5% copper. The district is one of promise.

Socorro County

(Special Correspondence.)—The Pacific mine is optioned to the Socorro company by the Oaks Co. The shaft is being re-timbered and other underground and surface preparations made for extensive production. An aerial tram to the Socorro company's mill will be completed within 60 days, when it is proposed to ship from 50 to 75 tons of ore daily for reduction.

NEW MILL OF THE BURRO MOUNTAIN COPPER CO., TYRONE, NEW MEXICO.

At the Confidence mine the old ore-dump is being sampled with a view to shipping to one of the local custom-mills.

Installation of a large double-drum electric hoist has been completed by the Ernestine Mining Co. Skips have superseded ore-buckets in the shaft. The company has been a constant producer of gold and silver for over 11 years.

The Socorro Mining & Milling Co. is treating over 200 tons of ore daily at its plant, with a product of around two tons of gold and silver bullion per month, in addition to several tons of high-grade concentrate.

Development of the Eberle mine is conducted by the Oaks Company. The last shipment of ore to custom-mill contained 47 tons averaging $17 per ton.

The Oaks Company recently took a bond and lease on the south half of the Clifton mine from the Socorro company. Operations will be increased as rapidly as possible, and the ore shipped to the Socorro company's mill.

Mogollon, June 5.

UTAH

Beaver County

All mining districts in this county are busy, many shipping ore and reporting favorable developments. Rich lead ore has been found in the Antelope Star mine in the Bradshaw district.

Juab County

The Gemini company of Tintic paid last week a dividend of $5 per share, or $25,000. The monthly output is 2000 tons of $30 to $35 ore. Over 100 lessees are working.

In April the Chief Consolidated's profit was $69,000. Dividends are at the rate of 20% per year.

Salt Lake County

The Fortuna Mining Co.'s property near Bingham has been sold by S. Bamberger and others to Le Roy Eccles and associates of Salt Lake City and Ogden for $250,000. The mine contains copper ore, but has been closed for some time.

The American Fork district is busier than ever, nearly all roads being suitable for haulage of ore and supplies.

As soon as the machinery is in place, the 4000-ft. adit of the Wasatch Mines Co. in Little Cottonwood district will be started.

Summit County

At the Silver King Consolidated, Park City, the aerial tram is under construction, to connect the mine and new mill. A modern mill is to be erected by the Traylor Engineering company. Slime will be treated by flotation. To separate iron from the zinc a selective process has been devised.

WASHINGTON

Stevens County

The region in northern Washington, particularly in this county, is responding more to the revival of interest in the mining industry than any other part of the North-west, not even excepting the Coeur d'Alene of Idaho, according to Sidney Norman. There is greater activity in Northport, where the Northport Smelting & Refining Co. recently began operating its new smelter, than ever before, not even excepting the period when the old Le Roi smelter was in operation, according to Francis A. Thomson, head of the School of Mines at the Washington State College, who, with a party of his students, is investigating conditions in the Stevens County mineral belt. Samuel James is in charge of the lead smelter.

Settlements at the Trail smelter for ore and concentrate from the United Copper mine near Chewelah during April totaled $32,000. Resumption of dividends is expected in July. The mill treats 225 tons of ore daily.

A Spokane syndicate, headed by Walter Nicholls, has pur-

chased 200,000 shares of the Electric Point Mining Co. from J. Peeper of Coeur d'Alene, Idaho, for $125,000. The Electric Point mine is 11 miles south-east of Northport, at an altitude of 5000 ft. A considerable quantity of high-grade lead ore is ready for the smelter when the road to the State highway is completed.

CANADA

British Columbia

Dividends paid in May totaled $274,977, of which $224,977 was from the Granby and $50,000 from the Standard. June payments are as follows: Hedley, $60,000; Rambler-Cariboo, $35,000; Standard, $50,000; and Crows Nest Coal, $93,189, a total of $238,189.

In the first five months of the year the Trail smelter has received a total of 203,561 tons of ore from 80 different mines. The Ben Hur and Knob Hill at Republic, Washington, sent 2099 and 1296 tons respectively.

Californians have bonded a gold property on Bayonne mountain, south of Nelson, for $142,000. J. McNichol of Butte put the deal through.

The Bayonne gold mine, in the Sheep creek region, owned principally by James W. Gerard, U. S. ambassador to Germany, and Thomas Hickey of Butte, Montana, has been taken under option by Philadelphia people, for a reported price of $300,000. The Bayonne is a splendid property with nothing against it but its remoteness from transportation, it being situated in the mountain range between the Salmon River valley and Kootenai lake, almost due west of the Sheep Creek camp. The government of British Columbia has promised to contribute liberally to the construction of a first-class wagon-road to the mine any time the owners gave assurance that they would put the property on a firm producing basis.

Ontario

Silver production of the Kerr Lake mine in April was 225,423 oz., the highest since 1910. The profit was $98,000.

In the period ended April 21 the Hollinger mill treated 42,673 tons of ore, at a cost of $1.895 per ton for mining and 95.7c. for treatment.

In the first quarter of 1916 the Vipond produced 11,816 tons of $5.24 gold ore. The 86.5% recovery was equal to $4.53 per ton, while costs totaled $4.51. There was a loss of $355 in the period. Reserves are 91,000 tons valued at $688,591.

KOREA

March details of the Oriental Consolidated company show that the plants treated 26,918 tons of ore for bullion worth $136,258. Recovery at the Maibong tube-mill plant was 91.8%; at the Taracol cyanide-plant, 79%. The spring has been dry, so the steam electric plants are in use until rain comes.

MEXICO

Exports from Mexico through the 'ports' of Agua Prieta and Naco during May were ₱1,985,400 and $2,256,240, respectively. The total tonnage was 14,078. Nacozari dispatched 10,123 tons. El Tigre sent 5843 lb. of silver-gold precipitate.

Greene-Cananea in Sonora is producing copper at the rate of 66,000,000 lb. per annum.

Hidalgo

From 23,148 tons treated during April the Santa Gertrudis company made a profit of $120,000. For the first quarter of 1916 the mill treated 67,352 tons, yielding $566,000, of which $274,000 was profit. Development covered 3996 ft., 1622 ft. in profitable ore. The 20th level interior counter shaft is down 365 ft. on the incline below the level. The vein on No. 22 will soon be opened, about the end of June. The plant worked at 67% capacity, 78% during March. Labor is more plentiful; timber is scarce, but is being railed from El Oro. Interesting experiments are being made with a ball-mill and flotation concentration, both of which show favorable results.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

Gardner Williams is at Santa Cruz.

E. S. Pettis is now at Chickagoff, Alaska.

J. Malcolm Maclaren has returned to London from Korea.

T. F. Cole of Duluth is to reside permanently at New York.

W. Spencer Hutchinson has spent several weeks at Oatman, Arizona.

R. E. Hore, editor of the *Canadian Mining Journal*, has been at Cobalt.

Nelson Dickerman has returned to San Francisco from Colombia.

O. B. Perry, consulting engineer to the Yukon Gold, is here from New York.

W. F. Stevens is superintendent of scheelite mines near Lovelock, Nevada.

O. M. Bilharz has moved his office from St. Louis, Missouri, to Miami, Oklahoma.

F. Lynwood Garrison sails by the *Vasari* from New York on June 17 to Brazil.

F. K. Brunton is on the staff of the A. S. & R. Co.'s Garfield smelter, in Utah.

Charles H. White, professor of metallurgy in Harvard University, is here on his way from Oregon.

J. Power Hutchins was in the Donetz anthracite region recently and has now returned to Petrograd.

Robert E. Cranston is at Butte, whither he will go periodically, under retainer with the Anaconda company.

L. F. Le Brun has been appointed general superintendent to the Linda Ventura Mines at Bluefields, Nicaragua.

Richard Hamilton has been chosen president of the Western Australian Chamber of Mines for the 19th consecutive year.

C. A. O'Connell has resumed charge of the Tough-Oakes mine at Kirkland Lake, Ontario, on his return from California.

Frank H. Probert announces his permanent address as the University of California, Mining Department, Berkeley, California.

Edgar A. Collins has been appointed manager of the Oceanic quicksilver mine in San Luis Obispo county, California.

William Dobbins, formerly with the Dominion Reduction Co. at Cobalt, has taken charge of the Good Luck mine near Arnprior.

Joseph Struthers has been appointed treasurer to the Federal Export Corporation and the Federal Shipping Company, New York.

Corey C. Brayton and Edwin R. Richards have opened an office, as mining and metallurgical engineers, in the Hobart building, San Francisco.

Peter Christianson, Elting H. Comstock, and Ervin W. McCullough, of the Minnesota School of Mines, have been touring Western mining districts.

John M. Hayes, assistant cashier of the Utah Copper Co., has been elected treasurer, and Robert C. Gemmell, general manager, has been elected a director.

Walter W. Bradley, mining statistician to the California State Mining Bureau, has returned from a trip through the southern part of the State, including the tungsten district around Atolia and the magnesite mines at Porterville.

The National Electric Light Association met at Chicago in the week of May 22. In its June issue of the *General Electric Review* the General Electric Co. of Schenectady has a special number of 148 pages devoted to the generation, distribution, and various applications of electric power, including mining.

THE METAL MARKET

METAL PRICES

San Francisco, June 13.

Antimony, cents per pound	37 50
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	7.25—8.25
Platinum, soft metal, per ounce	$74
Platinum, hard metal, 10% iridium, per ounce	$79
Quicksilver, per flask of 75 lb	$68
Spelter, cents per pound	21
Tin, cents per pound	46
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, June 13.

Antimony: 50% product, per unit (1% or 20 lb.)	$1.25
Chrome, 40% and over, f.o.b. cars California, per ton	10.00—12.00
Manganese: 50% product, f.o.b. cars California, ton	20.00
Magnesite: crude, per ton	7.00—10.00
Tungsten: 60% WO_3, per unit	30.00—40.00

At Boulder, Colorado, little tungsten is being bought. Lessees are selling at $10 to $12.50 per unit. One independent buyer is paying $25. The Primos Chemical Co. has advanced its price for lessees from $30 to $32, and will pay as much for 30% as 60% ore.

EASTERN METAL MARKET

(By wire from New York.)

June 13.—Copper is dull, though fairly steady; lead is inactive and weak, spelter is quiet and easier.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
June 7	66.62	May 2	71.45

June	56.43	49.03	....	Dec.	49.27	55.34	....

London reports a good tone in silver, in spite of rather wide fluctuations. Slackness of demand in competition with that for English and Indian coinage, coupled with re-sales and increased American supplies and Indian selling, caused a drop last week. Although rapid upward movements may not recur, a general demand for coinage is most likely. Shipments to India up to May 24 total £645,000, against £2,275,000 in this period of 1915. For Uruguay's new coinage 500,000 oz. has left New York, to be followed by 300,000 oz. more. Revolts in China may cause exports from that country to be less than ever.

COPPER

Prices of electrolytic in New York, in cents per pound.

On June 30 the following dividends will be paid: Ahmeek, $3; Champion, $6.40; Chino, $1.25 and $1; Kennecott, $1.50; Nevada Con., 37½ and 37½c., Old Dominion, $3; Phelps-Dodge, $2.50 and $3.50; Quincy, $4; Ray, 50c.; United Verde, 75c.; and Utah Copper, $1.50 and $1.50 per share.

Chino has appropriated $1,250,000 for plant enlargement.

May outputs included 1,517,000 lb. from the East Butte, 1,074,000 lb. from the Shannon, and 10,400,000 from the Inspiration.

LEAD

Lead is quoted in cents per pound, New York delivery.

For the sum of $8,000,000 the Granby Mining & Smelting Co. of Missouri has sold its properties to the American Zinc, Lead & Smelting Company.

Butte & Superior pays 75c. and $10 per share on July 1. New Jersey Zinc has declared an extra dividend of 5%, making 38% for the year on $38,000,000 capital. The cash payments total $13,300,000.

Anaconda's new electrolytic plant at Great Falls is expected to be ready early in September.

In the first three months of this year imports of zinc concentrate totaled 112,516 tons containing from 37.6 to 40.9% metal.

TIN

Prices in New York, in cents per pound.

Tin is quiet at 43.75 to 44.75 cents.

Eastern Metal Market

New York, June 7.

Zinc has been active in the past few days, and prices have advanced from ¼ to ⅝c. per lb., but it remains to be seen if the turn will he lasting.

All the other metals have been extremely dull.

In copper there has been little to indicate its actual level.

The A. S. & R. Co. reduced its lead quote ¼c., on the 2nd, but there has been little business, either before or since the reduction.

Efforts to tempt consumers into buying tin have been almost without results.

Antimony has continued to slump, and probably could be bought at 22c., duty paid. Two months ago its price was 45c.

Aluminum in unchanged.

New business in all metal, iron and steel lines is lighter, but there are plenty of orders in hand to keep the mills busy. Here and there prices are a trifle easier, as in pig-iron and structural steel. The production of pig-iron continues on an enormous scale, the total for May being 3,351,073 tons, or 108,099 tons per day, against 3,227,768 tons in April. A falling-off in production had been expected. It also is interesting to note that the country's production of ferro-manganese and spiegeleisen last month was the largest on record, amounting to 35,844 tons.

Machinery is moving steadily, though at a slower rate. Following the example of Great Britain, Russia has taken steps to curb speculation, and exports to Russia are retarded by strict regulations. Russia demands the name of the ultimate consignee, and various other data, also exacts a charge of $50 to cover cable tolls. Ocean-freights are somewhat lower, but irregular. No new munition orders are reported.

COPPER

The market has been dull to the point of stagnancy, one effect of which has been to cause the prices for future and prompt deliveries to draw closer together. In fact, it is questionable how much of a premium a prompt delivery would command today. Most of the metal which has been offered in recent days has been in second-hands, not a little of it belonging to consumers who over-bought, and now see an opportunity to sell at a profit, buying again later to make up any deficiency in their needs, at a lower price. Offering of this sort would soon disappear should the market show an upward trend. Near-by electrolytic probably can be obtained at 28c., cash New York, and future positions at near 27.75c. There is hardly enough doing to determine how the producers would act. Lake is purely nominal at about 28.25c., cash. The extent of the dullness is indicated by the fact that sellers are asking for bids. The London market for electrolytic was quoted June 6 at £142, an advance of £2 over the preceding day. One influence which makes for dullness is the uncertainty which prevails as to the ultimate effect the limiting of trading at London will have. The effort of the British government to suppress speculation was referred to a week ago. It was predicted that trading in standard copper would cease, but quotations of standard tin and copper continue to reach here. Exports to the 6th totaled 6619 tons. Copper in manufactured form is going abroad in large quantities.

ZINC

Last Friday (June 2), with the New York quotation down to 13c., and that at St. Louis at 12.75c. both for prompt delivery, the bottom of the market appeared to have been reached, and a turn was taken for the better. Yesterday prompt was about 13.62½c., New York, and 13.37½c., St. Louis. Since Friday a great deal of zinc has been purchased. The great question is whether consumers will continue to buy. Among the purchasers were galvanizing interests who had long been out of the market, and whose operations will speedily come to a halt again if prices advance too rapidly. On the 2nd fourth quarter was done at 10.50c., St. Louis, and the entire last half at 11.25c. Yesterday last quarter was up to 11.12½c., and last half at 11.75c., St. Louis. A strike of hoistmen in the Joplin district served to further strengthen the market, but this trouble is reported as about over. If prices for the refined metal do not advance, it is pretty certain that ore prices must come down. Methods of curtailing the production of ore have been discussed, according to report. The brass mills are well supplied with spelter for the orders they have in hand, and the premium on special grades of zinc is decreasing. It may be stated as a certainty that Europe will require large quantities of spelter in the not distant future. It was largely foreign buying that gave the market its better aspect last Friday. Exports in 6 days totaled 423 tons. The London quotation for spot on the 6th was £76.

LEAD

As was expected, the A. S. & R. Co. reduced its quotation on June 2. Late on that day it announced a reduction from 7.50c., New York, to 7c., and from 7.42½c. to 6.92½c., St. Louis. Prior to the reduction the market was dull, and there has not been much change since. Outside sellers have shaded the A. S. & R. Co. quotation about 5 points since the decline was announced, but have not obtained much action from consumers. Previous to the decline, the Independents were cutting deeply in an anxious attempt to get business. On June 1 foreign buyers took a few lots of 200 and 250 tons each. The market today is uncertain and unsettled. Exports from June 1 to 6 totaled 502 tons. The London spot quotation on the 6th was £32.

TIN

Except for a little business on June 1 and 2 the market has been extremely quiet for days, and prices have steadily declined. The quotation for spot Straits yesterday was 44.25c., while Banca could be had at 43.50c. The supply of Banca has been pretty well absorbed, but more is on the way to this country. Offerings at concessions have been made in the effort to induce business, but they only served to make consumers more timid. Deliveries into consumption in May were large, amounting to 5455 tons, of which 1255 tons came by way of Pacific ports. The total of deliveries since January 1, 25,223 tons, is an increase of 6982 tons over the same period of 1915. In stock and landing, on June 1 was 2468 tons. So far this month 1265 tons has arrived, aand there is afloat 3617 tons.

Tin ore from South America continues to arrive here, but is finding no market, and stocks are accumulating. The opinion is expressed that shipments from South America should be discouraged.

ANTIMONY

Prompt Chinese and Japanese is quotable at 23c., and it is probable that 22c., duty paid, would not be declined. There is a surplus of the metal, and no one seems to want any, except, perhaps, small quantities. There is report of large foreign inquiries, but these have not taken form sufficiently to bolster up the market. Needle antimony has been offered for spot delivery at 18c. per lb. without finding buyers.

ALUMINUM

The quotation for current deliveries of No. 1 aluminum, 98 to 99% pure, is unchanged at 58 to 60 cents.

COMPANY REPORTS

HOLLINGER GOLD MINES, LIMITED

A comparison of the years 1914 and 1915 at this Porcupine, Ontario, mine, shows the following results: ore treated, 208,936 and 334,750 tons; gold recovered, $2,688,355 and $3,169,814; and dividends paid, $1,170,000 and $1,560,000, respectively.

The report for 1915 is accompanied by that of the general manager P. A. Robbins, recommending consolidation of this company with the Acme and Millerton companies, and certain property of the Canadian Mining & Finance Co., which has since been done, forming the Hollinger Consolidated Gold Mines, Ltd. This was briefly discussed in the PRESS of May 20. The combined area of the properties is 440 acres. In 42 months the Hollinger produced 728,172 tons at a profit of $6,078,925, of which $4,170,000 was disbursed; and the Acme $1,036,008 of bullion from 106,486 tons in 10 months. The Millerton and claim 13,147 are not yet producing gold. The consolidation will result in economies, and minimum loss through the vagaries of geological phenomena, some of which are shown on the accompanying plan. The rocks are of the Keewatin series of pre-Cambrian age. An estimate of the relative values of Hollinger and Acme properties under various possible conditions gives 4,520,800 tons of $7.82 ore in the former and 5,909,230 tons of 2c. less value in the latter. This is based on a depth of 1400 ft., crediting each vein with 80% of the tonnage indicated, and an average value equal to 60% of the value obtained at the surface. The Millerton may contain 400,000 tons of $6.50 ore, and claim 13,147, a total of $200,000. The Acme has a chance of yielding less ore than calculated on account of two tongues of quartz-porphyry, that probably join at a depth of 1500 ft. This rock does not contain profitable ore, save where it contacts with schist. Profit in the reserves is $13,708,227 for the Hollinger and $15,777,455 in the Acme, Millerton, and claim 13,147, a difference of about $2,000,000 in favor of the Canadian Mining & Finance Co.'s holdings. For plant and development the Hollinger has an investment of $1,425,000, and the Canadian company $850,000. The Hollinger has net current assets of $744,743. In the new company of $25,000,000 capital—5,000,000 shares—Hollinger shareholders receive 2,400,000 shares (four for each one in the old company), Acme 2,100,000, Millerton 200,000, C. M. & F. Co. 100,000, and 200,000 to treasury. The Hollinger mill is now treating 1900 tons daily, for a profit of $280,000, of which $240,000 will go in dividends. The mill is to be increased to 3500-ton capacity, at an expenditure of $750,000. It has taken five years to amalgamate these properties, the geologic research, underground work, treatment problems, centralizing of plant, etc., having all been done with this end in view.

During 1915 development in the Hollinger totaled 10,805 ft., with 8378 ft. of diamond-drilling, down to a depth of 100 ft. Ore reserves are estimated at 1,600,800 tons, worth $10.02 per ton, an increase of 437,840 tons, but $1.47 less in value. Mining cost $2.183 per ton.

The mill gave a good account of itself in treating 334,750 tons of Hollinger ore, assaying $10.11 per ton. Gold recovered was worth $3,169,814. The cost of treatment was $1 per ton. Extraction averaged 96.04%. All costs totaled $3.98 per ton, against $5.21 in 1914. There were 735 men employed.

PLAN SHOWING VEIN OUTCROPS AND SURFACE GEOLOGY OF THE NEW CONSOLIDATION AT PORCUPINE, ONTARIO; THE HOLLINGER CONSOLIDATED GOLD MINES, LTD.

TONOPAH MINING CO. OF NEVADA

This company operates at Tonopah, Nevada, and controls the Tonopah Placers Co. of Breckenridge, Colorado, and the Eden Mining Co. in Nicaragua. The first dividend has been paid by the Colorado property, while the Central American mine is having a mill erected as fast as possible. The report of the Tonopah company is for the year ended February 29, 1916; future reports will coincide with the calendar year. The remarks of the superintendents at the mine and mill, W. H. Blackburn and F. F. Heydenfeldt, respectively, are brief.

Ore reserves amounted to 53,493 tons, averaging $14.93 per ton. Mining cost $4.31 per ton. There were no important changes in mining and milling methods. There was treated 136,246 tons of ore averaging $13.66 per ton. The recovery, based on net smelter returns was 90.3%, a gain of 1.3%. Cost of treatment was $2.94 per ton, a decrease of 7.7c., in spite of increased prices of supplies. Costs in all departments were $7.78 per ton, and profit $4.77, metal losses being $1.11 per ton.

Net earnings were $468,331, plus $314,733 from dividends in banking, placer, power, and railroad companies, also interest, etc., making $783,064 available. The surplus at the beginning of the year was $3,860,244; at the end $3,704,259. Dividends (4) totaled $800,000, making $13,300,000 to date.

Gold recovered by the Tonopah Placers Co. amounted to $479,018, of which $216,980 was profit.

NEW YORK & HONDURAS ROSARIO MINING CO.

The thirty-fifth annual report of this New York company operating in Honduras, Central America, covers the year 1915. The low prices of silver affected profits considerably, however. 12% dividends, equal to $240,000, were paid and a substantial cash reserve, $66,578, maintained. The year's revenue from silver and gold was $1,191,761, making $21,172,967 since 1882. On January 1, 1915, the surplus was $994,368; on December 31, $990,510. The manager is A. R. Gordon, with F. H. Minard as consulting engineer, and A. G. Greeley as general agent. Grasshoppers damaged the crops, and supplies increased in price due to the War. All costs were $16.886 per ton.

Mine development amounted to 13,000 ft., a decrease of 2700

ft. About 20 veins are worked. Reserves are estimated at 343,716 tons, averaging $9.76 per ton, which is 75,262 tons less than in 1914. Development is to be pushed on the San Miguel vein, south of the West vein. Surface and underground geology was thoroughly studied to aid exploration. Mining cost ₱8.962 per ton, a decrease of ₱1.

The mill treated 117,790 tons of ore averaging 16.97 oz. of silver and 0.14 oz. gold per ton; the yield was 1,748,803 oz. and 15,211 oz.; recovery was 87.45 and 92.32%, respectively. When the ball-mill and thickener are erected the capacity will be increased from 355 to 380 tons per day. Oil flotation is being experimented with. Treatment cost ₱5.5992 per ton.

The rainfall was 72.06 in., giving plenty of power. Owing to a drought in the previous year there was plenty of labor available. The rate of exchange favored the company, being 7 cents U. S. per Honduras *peso* higher than in 1914.

AHMEEK MINING CO.

Underground work in this company's mine in 1915 amounted to 8594 ft., compared with 4587 ft. in 1914. The four shafts are respectively 2533, 2775, 2210, and 2158 ft. deep. Results generally were satisfactory. On No. 12 level of No. 2 shaft a large mass of copper is being removed from the intersection of the fissure and the lode, and during last year 1,488,000 lb. was extracted. A number of improvements were commenced at No. 2 shaft and ore-house. The latter will include two 24 by 48-in. crushers. Two more stamps were completed at the mill.

The past three years' results were as under.

	1915	1914	1913
Ore treated, tons	948,874	590,519	383,749
Copper content, pounds	23	23.1	24
Copper extracted, pounds	21,800,492	13,634,605	9,220,874
Cost, cents per pound	7.96	9.71	13.30
Revenue	$3,999,801		
Profit	2,264,882		
Dividends ($18 per share)	1,650,000		

The balance at the end of 1914 was $968,772; at the end of 1915, $1,583,654.

QUINCY MINING CO.

During 1915 development in this Michigan mine amounted to 27,340 ft. At the bottom of the mine is more mill ore and mass copper than for several years. Air-blasts have been more or less numerous throughout the year, and have given continued trouble and hindrance to the output; yet they have not been of an especially serious nature or of great magnitude. The necessary repairs caused by their damage have not been on a large scale, although their cost, combined with the loss incurred by delays, has been considerable.

Results were as follows:

	1915	1914	1913
Ore treated, tons	1,269,000	.....	.....
Refined copper, pounds	22,054,813	15,356,380	12,184,128
Revenue	$3,983,985	$2,054,622	$1,921,199
Profit from all sources	1,873,674	205,593	76,160
Dividends ($8 per share)	880,000	55,000	412,000
Surplus, inc. previous one	$1,664,956	$897,531	$746,938

Copper was sold at an average of 18c. per pound.

The smelter has been busy throughout the year, especially during the latter half of the period, owing to the increase in the amount of custom work, and it is now running nearly to capacity.

MYSORE GOLD MINING CO.

The 78-page report of this English company operating at Kolar, State of Mysore, India, is for 1915. The superintendent, R. H. P. Bullen, discusses the following points of interest:

Underground exploration covered 22,238 ft., a decrease of 4010 ft. There were 101.4 rock-drills used in the mine. The Edgar vertical shaft is 3024 ft. deep. At 3226 ft. in McTaggart's shaft 400 ft. has been driven on a well-defined quartz lode, averaging 36 in. in width and $14.80 per ton. A winze below this is down 90 feet on 55 in. of $20 ore. Ore reserves are estimated at 1,044,000 tons, an increase of 30,000 tons. Costs were reduced a total of 32c. per ton.

The mill crushed 305,000 tons averaging $13.14 per ton. The cyanide plants treated 245,866 tons of sand and 192,487 tons of slime, assaying $2.63 per ton, some being old material. The gold yield was 207,981 fine ounces.

The revenue was £880,168, of which £335,500 was paid in dividends. The rainfall was 39.67 in. Employment was given to 161 Europeans, 128 Anglo-Indians, and 9501 Indians, a total of 9790.

Results since 1884 are 4,525,871 tons of ore, yielding £17,060,587, and £8,100,594 in dividends.

ALLOUEZ MINING CO.

This is a Calumet & Hecla subsidiary, operating in Michigan. Development in 1915 covered 1485 ft. at No. 1 shaft, which is 3544 ft. deep; and 3373 ft. at No. 2, 3407 ft. deep. Stopes tributary to the former are up to the average grade, while those at No. 2 are a little better. New 60-lb. rails were laid throughout No. 1 shaft.

A comparison of the past three years is as follows:

	1915	1914	1913
Ore treated, tons	534,705	354,457	236,663
Refined copper, pounds	10,043,459	6,056,548	4,091,129
Refined copper per ton, lb.	18.78	17.09	17.29
Cost, cents per pound	9.31	11.18	12.09
Price received, cents per lb.	18.166	.....	.....
Gross revenue	$1,859,566	.....	.....
Operating profit	924,681	.....	.....
Dividends paid (2 of $1 each)	200,000	.....	.....
Quick assets	963,811	$363,823	.....

At No. 1 mill, at Point Mills, of two stamps, one is crushing Hancock ore. These are simple stamps. At No. 2 mill at Hubbell, one unit crushes Allouez ore, the other Centennial. Two new Nordberg compound stamps are being erected.

CENTENNIAL COPPER MINING CO.

This is a Calumet & Hecla subsidiary operating in Michigan, and notes on the mills are the same as those in the Allouez report below this one. Openings at No. 2 shaft, 4293 ft. deep, totaled 2366 ft. No. 1 shaft is 3821 ft. deep and is used entirely for men, material, and pumping. At No. 2, good ground was opened at No. 31 and 32 levels. On August 13 this shaft was badly damaged by fire.

Results during the past three years are as under:

Details	1915	1914	1913
Ore treated, tons	150,191	138,136	85,443

STANDARD SILVER-LEAD MINING CO.

This company operates at Silverton, British Columbia, with G. H. Aylard as general manager. Mine development covered 5749 ft. Ore extracted in 1915 was 39,447 tons. Of this, 3557 tons, averaging 54.69% lead and 93.43 oz. silver was shipped to smelters. The mill treated 35,920 tons, yielding 4804 tons of lead concentrate containing 59.84% lead and 97.98 oz. silver, and 4401 tons of zinc concentrate assaying 42.51% zinc and 23.04 oz. silver per ton. The cost of all departments totaled $5.44 per ton. The total income was $799,473, of which $510,430 was profit. The surplus, after paying $250,000 in dividends, was $260,430. Profits to date are $2,201,757.

INDUSTRIAL NOTES

Information supplied by the manufacturers

A New Direct-Current Generating-Set

A generating-set for marine or stationary service, and especially adapted for lighting or power service in small plants, and for exciters for large alternating-current generators in power stations is now on the market. It consists of an American Blower Co. single or double cylinder, automatic steam-engine, and a type SK direct-current generator made by the Westinghouse Electric & Mfg. Co., East Pittsburg, Pennsylvania, direct-connected to the engine-shaft. For lighting or power service the standard pressures are 125 and 250 volts. For this service generators are furnished having the compound field windings so proportioned that the same voltage is obtained at full load and no load. For special systems where 125 volts are required for lighting and 250 volts for power, the larger sized generators are supplied for three-wire service. These three-wire generators will take care of any unbalancing of the two sides of the system up to 10% of the full load.

The set is simple to operate and requires little attention. The generator is mounted on the same base with the engine to which it is direct-connected. The bearings, brushes, and commutators are the only wearing-parts. The engine is quiet in operation and has automatic lubrication by pump and gravity, with large cooling, settling, and filtering area. All wearing parts are easily adjustable, and perfect speed regulation is obtained.

This set is particularly well suited for use in isolated plants at mines and dredges, as well as for driving blowers, bucket-elevators, screw-conveyors, chain-drags, hoisting apparatus, cylinder driers, and centrifugal driers.

Commercial Paragraphs

The Sweetland Filter Press Co. has leased the entire fourth floor of the new Sperry building, Brooklyn, New York.

The E. H. Moyle Engineering & Equipment Co., Los Angeles, California, has moved its offices to Ninth street, where its works are situated and where an ore-testing plant will be equipped.

L. G. E. Bignell, formerly sales manager for the Denver Engineering Works, and for the past three years engineer for the Mine & Smelter Supply Co. at El Paso, has accepted a position with the Colorado Iron Works at Denver as sales engineer.

Bound in 'fabrikoid' (a leather substitute), one of its products, the E. I. du Pont de Nemours & Co. of Wilmington, Delaware, has published a 111-page book describing briefly its manufactures, whom they are used by and what for. There are 251 distinct commodities listed.

The Monarch Engineering & Machinery Co., San Francisco, claims to have perfected a Chilean mill in which automatic adjustments are obtained whereby a pulp of any practical degree of fineness can be delivered in one operation. The driving-spider is slidable on the drive-shaft.

Alternating-current generators, engine and belted types, are described in Allis-Chalmers Bulletins 1098 and 1099. Illustrations are given of the most important parts of the generators; also of actual installations, where gas, oil, and steam engines are used with the electric machines.

A 16-page booklet on graphite for cylinder lubrication—both steam and gas cylinders—by the Joseph Dixon Crucible Co. of Jersey City, gives concise facts about this important subject, also about lubricators that are made to use graphite alone or with oil. In one instance a reduction of 52.5% in lubricating cost was reported when using graphite.

Duntley electric grinders of various types are described in Bulletin E-39 of the Chicago Pneumatic Tool Co. These machines are especially adapted for use in foundries, machine-shops, structural-shops, and for grinding rails on railways. Bulletin 192 deals with stone tools, stone dressers, air compressors and equipment for yards where stone is cut to certain designs.

The constantly increasing tonnage produced by the Luckie 2 Tungsten Mines is causing that company to continue increasing its milling capacity. It has just given the Denver Quartz Mill & Crusher Co. the third order for Denver quartz-mills. The first equipment installed in the Luckie 2 mill in 1910 was supplied by the Denver company. The mill is in constant operation, 24 hours a day. The Luckie 2 is among the large mine and mill operators in Boulder county, Colorado.

The Montana Power Co. of Butte, Montana, has recently placed a contract with the S. Morgan Smith Co. of York, Pennsylvania, for four 15,000-hp. vertical hydraulic turbine units to operate under a head of 100 ft. These machines will be installed in connection with the Holter development on the Missouri river near Great Falls. The S. Morgan Smith Co. is also building for the Great Falls development of the Montana Power Co. two 16,000-hp. vertical units, which, together with the four recently installed, will make approximately 100,000 hp. in Smith wheels at the Great Falls plant.

Bulletin No. 70-C, from the Sullivan Machinery Co., Chicago, describes its class DR-6 mounted hammer-drill with water attachment. This has been on the market for the past 18 months or 2 years, giving unusual satisfaction for driving, tunneling, and a wide range of general mining work of the heavier drilling variety. Certain mechanical features distinguish this drill from others of the same general type hitherto made. These features include: single throttle control of air and water, absence of external valve-chest, small front-end rendering changes easy, and use of hand-operated lock-ring for releasing steel from the chuck. Other interesting features are fully described in the bulletin. This machine uses hollow round steel with lugged shanks. In the Joplin, Missouri, district, it is used for drilling the flat stope holes up to a depth as great as 16 ft., while in Barre granite on down holes, it has drilled as deep as 18 ft. successfully. The DR-6 is meeting with great success in such fields as Joplin, Butte, Deadwood, Jerome, northern Michigan, Alaska, and British Columbia.

The Ingersoll-Rand Co., New York, has recently issued three new bulletins as follows: Form 9023, 24 pages, 6 x 9 in., on 'Imperial' tie-tamping outfits. This apparatus had a gradual development under actual working conditions on some of the largest railroad systems in the country, extending over a period exceeding two years. It is comparatively new to the trade, but the railroads have been quick to appreciate the economy attendant on the use of one or more of them. The tamper is employed principally in the operations of laying new track, replacing old track, and surfacing existing track, but is further effective in special applications. It will produce equally effective results in any kind of ballast—stone, gravel, earth, cinders, chat, slag, etc. Form 3026, 40 pages, 6x9 in., catalogue on Ingersoll-Rogler class PRE duplex direct-connected electrically-driven air-compressors. Among the principal features of design may be mentioned the Ingersoll-Rogler valve, the clearance controller, direct-connected drive, improved-inter-cooler, and auxiliary water-separator. The catalogue is printed in two colors, and is profusely illustrated to show construction details. Four pages are devoted to pressure charts and tables showing sizes and capacities. Form 3312, 20 page, 6x9 in., catalogue on Imperial XB duplex power-driven air-compressors. Illustrated.

EDITORIAL

T. A. RICKARD, Editor

PREPAREDNESS parades prove, not so much the willingness to enlist, as the ability to organize; and that is no small matter. Moreover, these parades will impress Congress, which is looking for signs of public opinion.

MOST of the gold produced by the South African mines, at the rate of $16,000,000 per month, is now being shipped to Canada by way of Japan, instead of going to London. The output of the Rand continues to grow; in May it was 770,000 ounces, and for the first five months of this year the total is 3,867,000 ounces, compared with 3,651,000 ounces in the corresponding period of 1915.

AT this time of writing, the Mexican crisis is approaching the point of explosion. The exchange of notes portends a rupture, for we question whether Carranza can acquiesce in the continuance of American military occupation without inciting a revolt among his own followers. Similarly, the President has declared himself in terms rendering it impossible for him to comply with Carranza's demands. Intervention appears inevitable.

IRON being the barometer of industrial conditions, it is satisfactory to note the movement of iron ore on the Great Lakes. Navigation opened in April, and to the end of May there was shipped to lower lake ports a total of 10,107,991 tons, compared with 5,517,191 tons in the corresponding period of 1915. During May the production of iron in the United States reached a total of 3,351,073 tons—a record—as compared with 2,263,470 in May last year and 2,822,217 in 1913.

FIRE-INSURANCE is a matter liable to be lightly regarded until the opportunity for remedying carelessness is gone. The recent burning of a mill belonging, fortunately, to one of the most prosperous mining companies in California, prompted Mr. Charles T. Hutchinson to write the article, appearing in this issue, on the subject of insurance. He writes as an engineer, not an agent in quest of premiums, for he is manager of our business department. The reader will note that the counting-house of this publication can swing a pen to literary purpose.

HIGH ocean-freight rates are having sundry unexpected effects, one of which is the fact that it has become profitable to tow 3000-ton sailing-vessels from San Francisco to Balboa, the Pacific terminal of the Panama Canal. The voyage, under such conditions, takes 18 days. We are informed that one tug, the *Hercules*, well known at this port, is to tow a vessel all the way to New York, through the Canal. More than a week is saved between Cristobal, the Atlantic terminal, and New York by towing a vessel, as compared with propulsion under its own sails, besides a similar saving in the Pacific portion of the voyage.

BROKERS' circulars continue to exclaim at the low price of copper-company shares as compared with the increase of dividends. Surprise is unnecessary. No mystery exists. The public is aware that the high price of copper is abnormal, being due to conditions that are not likely to persist. In valuing copper prospects, we note that many engineers use 15 cents as a price on which to base estimates of future profit. This figure is slightly above the average of the period preceding the War, but it is fully justified by reasonable expectations. We expect a price higher than 15, but considerably lower than 28, when peace is restored.

ACCORDING to Mr. William C. Redfield, Secretary of Commerce, the proportion of industrial products consumed for warlike purposes represents only 20% of the total volume of American exports during 1915, but as $190,000,000 of similar material was exported in 1913, it may be concluded that only 15% is actually War business. Labor in the United States is benefiting enormously from the War. For example, the Industrial Commission of the State of New York reports an increase of 21% in the number of employees in April as compared with a year previous, while concurrently the total of wages has increased by 37%. Wages have increased faster than work.

INDEXERS might have had trouble with Mr. F. H. Mason's article on Cobalt if we had not added a subhead of an explanatory character. It is true the mining district of Cobalt gains from the increased use of the metal cobalt in the arts, but the reader who is seeking information concerning the one does not care to be sidetracked onto the other. Mr. Mason writes on his subject with his customary skill. Owing to our Procrustean method of making articles fit pages or columns, as the case may be, we had to omit a friendly reference to Mr. Herbert T. Kalmus, who is conducting research on cobalt at Queens University, Kingston, Ontario, and has published sundry admirably lucid descriptions of his work. We are glad to make the acknowledgment for Mr. Mason.

OUR compliments to Mr. H. E. McCray, editor of 'The Engineer,' the 1916 annual publication of the students in the Michigan College of Mines. It does

credit to all concerned. Among other features we like the highly intelligent faces of the Tau Beta Pi men. Looking through the directory of alumni, the fact is brought home that the Houghton School has given the mining industry a large number of useful men, among whom we recall personally W. E. Parnall, W. J. Uren, John Hoatson, John G. Kirchen, W. M. Cameron, W. L. Honnold, A. E. Seaman, F. T. Greene, Charles W. Wright, Scott Turner, Louis A. Wright, and P. B. McDonald, besides many others known to us by repute.

ON another page we give part of a letter written by a mining engineer who has done effective work on the Italian battle-line. He would be the first to insist that this is the sort of duty that has been done well by many of our profession serving with the various armies in Europe. We call attention to the large blast described, by which 15,000 tons of rock and earth was blown skyward by 5 tons of gelatine containing 92% nitroglycerine.

ELECTION of Messrs. Robert C. Gemmell, C. B. Lakenan, John M. Sully, and Louis S. Cates to the boards of directors respectively of the Utah, Nevada Consolidated, Chino, and Ray Consolidated copper companies indicates that it is becoming recognized as desirable to associate the resident manager of a large mining enterprise with the general direction of affairs; in short, financiers are appreciating how much their industrial success depends upon the man actually in charge of operations.

THE American Zinc, Lead & Smelting Co., usually abbreviated to the American Zinc Co., has absorbed the Granby Mining & Smelting Co., which owned zinc and lead mines and smelters in the Missouri and Kansas region. The Granby was an old company owning large tracts of mineral land in south-west Missouri, besides coal-lands in Illinois, its entire 'net quick assets' being reckoned at $2,750,000. The American Zinc Co., which is owned largely in Massachusetts, made a profit in 1915 of $5,293,878 from wide-spread operations, including zinc mining and smelting and sulphuric-acid manufacture, in Tennessee, Missouri, Kansas, and Wisconsin. The famous Mascot brand of spelter, produced from mines in eastern Tennessee, is free from lead and therefore is suited for making the brass used in cartridges. Among the company's activities is the smelting of 8000 tons of zinc concentrate per month from the Butte & Superior mine, in Montana.

JAPAN is the second greatest copper-producing country in the world, ranking next to the United States. Her annual production is about 150,000,000 pounds, a total approximately equal to the 1915 output of Utah Copper or the Phelps, Dodge & Co.'s mines. In other words, Japan contributes about 7½% of the world's production as compared with the 60% produced by this country. During 1915 a relatively large proportion of the Japanese production went to Russia, and a considerable portion of the remainder was exported to the United Kingdom, the United States, and France; the customary exports to China, Germany, and India being much reduced. In fact, instead of exporting copper to China, Japanese speculators imported Chinese brass coins in large amount and melted them for the copper and zinc. A noteworthy part of Japan's new production of zinc is thought to have been derived from this melting of Chinese coins.

ON June 14 the alumni of the Massachusetts Institute of Technology assembled simultaneously in 35 different cities in order to take part in a celebration of the semi-centenary of the 'Tech.', and the completion of the new buildings on the Charles river, at Cambridge. All of these 35 assemblages were put in touch with each other and the proceedings at Boston by means of an elaborate system of telephonic communication, in which 5000 men were able to participate. Among the speakers was Mr. Michael I. Pupin, the inventor of the coil that made long-distance telephony practicable, and Mr. J. J. Carty, who was the engineer to put the idea into successful service. Some of the speakers were heard in San Francisco as clearly as if they were sitting across the table, thanks to their excellent enunciation. The affair was a great success and afforded a scientific method of celebrating an event that will give pleasure to many outside the alumni association of the Institute of Technology, which includes many of our most capable mining engineers and metallurgists.

TUNGSTEN remains fairly steady at $30-35 per unit. We understand that one reason for the weakness of the market is the fact that a group of speculators at New York had over-loaded themselves with concentrate in expectation of higher prices. The recent drop has had the effect of stopping importation from South America. The Japanese wolframite that has been coming to this country is dirty, from a metallurgical standpoint, for it contains bismuth, antimony, and other deleterious ingredients. On the whole, the scheelite from Atolia is about the cleanest product sent to the makers of tool-steel. Several alleged discoveries in California and Arizona have proved grossly exaggerated, the first sampling having been misleading. Another curious feature of tungsten mining in the West has been the development of ore-stealing; in the Atolia district several men have been caught red-handed and it appears that agents of the steel companies stimulated theft by offering $85 per unit during the period of maximum prices.

DISCUSSION in this issue starts with a thoughtful letter by an obviously experienced metallurgist in Bolivia. Mr. Söhnlein's opinions are so well expressed as to compel attention. In the second contribution a mining engineer not long ago in British Columbia discusses a subject concerning which we have written more than once. His way of stating the case is interesting, but he will pardon us for suggesting that it reads like that of a miner that quit mining to go ranching and has

found the latter so little attractive that he turns back to the digging of ore. The public that buys 10-cent mining shares is the same public that dabbles on margins in other markets. We agree as to the futility of warnings, if for no other reason that such small speculators do not read a technical periodical like this, which concerns itself mainly with the more serious work of the mining industry. The 'game' and the 'industry' are only related by marriage. That some of the money raised by gamesters is instrumental in discovering real mines, that is, profitable holes in the ground, is not gainsaid, just as some of the money won at Monte Carlo may find its way to the support of a hospital; on the contrary, many a wild-cat *in esse* is a mine *in futuro;* one of the essentials to finding ore is exploration, and that much the digging of a wild-cat does contribute. We mining engineers must not sneer too much at what appears to us to be misdirected effort, having modest regard to the large proportion of well-directed effort that fails. This concession being made, we agree with Mr. Percy Williams that the fundamentals to success in mining are money and an experienced man to direct the spending of it—a man experienced both in mining and the spending of money. We publish three contributions dealing with the flotation process as expounded in our columns. Mr. G. D. Van Arsdale defines 'froth' and discusses the rationale of it in a useful way; he also comments upon the essentials of a 'film.' Mr. Alfred Stansfield's explanation reminds us of Dean Swift's definition of an archdeacon as a man who performs archidiaconal functions. Mr. H. W. DuBois throws light on the treatment of sundry copper ores, particularly those that are coated by products of oxidation, and the use of sulphuric acid for the removal of such a coating. Just as we were going to press we received the letter from Mr. J. W. Swaren, notifying us, and our readers, that he is about to organize a volunteer engineer corps, with the concurrence of Army officers in San Francisco. Mr. R. S. Burdette's information concerning the Mexican silver dollar is timely, for it may be that the peso will be at a severe discount in a few days.

Employer and Employee

Among the signs of the times we note a better understanding of the relation of capital to labor, or, to be more precise, between the employer and the employee. Two departures from custom may be instanced, the first being the allotment of a portion of dividend as a reserve fund for distribution among employees, as has been done by the directors of the Nevada Wonder Mining Company. The scheme is to set aside a sum equal to 5% of the dividends paid annually and distribute it among the men that have been in the employ of the company for one year or more. The object, as stated by the directors, is "to establish a co-operative system by which the employees of the company may participate in the profits." As our readers are aware, the U. S. Steel Corporation set aside a large block of stock for purchase, at a relatively low price, by its employees, and thereby introduced a profit-sharing system, out of which the men must have done well. It is not unusual for companies to add a bonus to the Christmas pay-roll, and most of the big copper companies have established a sliding scale of wages based on the price of copper, but the Nevada Wonder plan is an example of direct profit-sharing by a mining company. The second incident to which we refer is the opening of a town-club at Plymouth. The building is the gift of the Plymouth Consolidated Gold Mines and is meant for the use not only of those working in that company's mine, but of the townsfolk generally. The management is in the hands of a committee of seven members of the club, four of whom represent the employees of the company and three represent the other residents in the town. The dues are $1 per month. The purpose, besides providing comfortable quarters and orderly amusement, is to bring the whole community together on a friendly foundation. A 'relations' committee is chosen by the members to discuss and adjust grievances or misunderstandings; in short, instead of the company's interest being treated as alien, it is made a part of the local welfare. Trivial differences between employer and employee will be adjudicated before they become serious; also any attempt by avowedly anarchistic organizations, like the Western Federation of Miners, to make trouble will be rendered fruitless by the growth of a community spirit, likely to help the mine management so long as it shows itself reasonable and fair to all concerned. After all, the people of the town in which, or near which, a mine is situated have a direct interest in its welfare, in the continuity of its operations, and the maintenance of its success. We welcome anything that will destroy the idea that the employees are helots and the employers satraps of industry. Co-operation is essential to industrial success and fair-dealing is the direct way to ensure such co-operation.

Preparedness

Insistence upon proper preparation for national defence has been made a plank in the platforms of both political parties; therefore it may be considered a non-political subject. We propose to discuss it in relation to the engineering profession. In the first place, the engineer is a man and a citizen, he has duties to the community and the country, and he is prepared to serve both. Indeed, one of the faults of the age is that it makes too much of the lawyer, with his gift of talking, and too little of the engineer, with his ability to do things that are of the greatest practical usefulness. This is an engineering age and it is high time that professional talkers were retired to their proper place in the economy of things. Local and sporadic efforts have been made to find scope for the talent of the non-military engineer in any scheme of national mobilization. Of these the most promising is that which is now in the hands of a committee representing the national engineering societies. Mr. William Barclay Parsons is chair-

man of this committee, which has received proper consideration from military headquarters at Washington. At the instance of the War Department a bill has been introduced in Congress to provide for the organization of a Reserve Corps of Engineers, which is to supplement the Engineer Corps of the Regular Army in the event of war. This Reserve Corps is to be formed along lines similar to the existing Medical Reserve Corps and in conjunction with the latter, with the purpose of making provision for a supply of officers able to superintend engineering operations of the diversified kind incidental to modern warfare, such as the building of railroads, motor-roads, bridges, gun emplacements, and trenches. The technical men recruited from among civil engineers will also bring to bear their wide knowledge of the manufacturing and contracting businesses of the country, all of which would be called upon, to the utmost of their resources, in time of war. We used the term 'civil' engineer in its true sense, which is 'non-military.' When the profession was yet insignificant in point of numbers it was organized, both in England and in America, as a society of civil engineers, in distinction to the military branch of the profession. Since then the mining, mechanical, electrical, and chemical branches have developed and grown so as to require organizations of their own, all of which are included under 'civil' when discussing military science. Here we may remark that mining itself has a military origin, that the word 'mine' had a military significance before it became industrial, and that the European war has demonstrated the full importance of the mining engineer, whose tunneling, mining, and counter-mining are today among the most dangerous and most effective of the operations at the front. It is proposed to give commissions for a period of five years, renewable at the discretion of the Secretary of War, so that the unfit may be retired without friction. Two weeks instruction yearly is to be the minimum; and while this may seem little enough, it is to be remembered that the work to be done in war is much the same as in peace, save for minor differences that can be apprehended by an intelligent and willing learner in short order. It is hoped, of course, that the younger men will go to the summer camps and avail themselves of longer periods of training, as circumstances permit. Meanwhile one fundamental purpose will be fulfilled, namely, the mobilization of engineering experience. The national resources in this kind of human material will be recorded by a card-index system, and presumably the help of the engineers will be utilized further in the obtaining of further data concerning labor skilled in construction work of every description. Similar duty is being done by the Advisory Committee to the Naval Board in other departments of industrial activity. Thus the result will be, if the plan is carried out to full fruition, to mobilize the entire resources of the country in time of peace so as to know where to find what is wanted on the sudden emergency arising from a declaration of war.

Whether the Army or the Navy as it now exists could protect the country against attack, it is not necessary to discuss. It is past discussion. We venture to point to the fact that the United States, by reason of its enormous length of coast and the tapering of its continental area southward, is in effect a peninsula. Again, by reason of the only passage by water, except around Cape Horn, being the Panama Canal, we have there a highly vulnerable artery of maritime communication. In short, the United States is vulnerable along an enormous front.

Another phase illuminated by events in Europe is the dependence of armies and navies upon factories and workshops. Even the systematic preparedness of Germany under-estimated that basic factor, so that while an army of unquestioned efficiency and numbers was ready at the outbreak of war to take an instant offensive, it is now becoming evident that even Germany was not adequately organized to supplement her military preparedness with the requisite supply of munitions. It is probable that in future wars, as in this, a prime requisite will be a manufacturing industry so organized and so flexible as to be ready to produce whatever is wanted, in the way of warlike material, with the minimum of delay. The preparation will be useful for industrial competition as well as war; it will be a preparedness for conditions that cannot be anticipated. Just now, it looks as if an efficient aerial navy might prove the most effective defence against attack by land or sea. Nevertheless, neither armies, ships, nor aeroplanes can be effective unless the right kind of man is behind the gun. Some sort of training is required, even if Mr. Edison's prophecy be fulfilled and a machinist behind a machine prove to be the most destructive weapon of warfare. Whether you call him a 'machinist' or a 'soldier' matters not; he must have a sense not only of initiative, but of discipline, and that is not taught or learned in three weeks, especially in a genuine democracy.

One more point may be mentioned. No matter what the weapons or apparatus of war, they must be made of metal. The mineral resources of the United States are such as to ensure an adequate supply of nearly all the metals required for the purpose, and substitutes for those that we lack should be found; for instance, tin and nickel. Tin, used chiefly for plating and solder, is not obtainable in quantity on this continent, at least north of the Rio Grande. Nickel is scarce in the United States but plentiful not far across the line in the territory of our friendly neighbor, Canada. Of most of the other essential metals, particularly copper, zinc, lead, and steel-making substances, we have a superabundance. However, this phase of preparedness should be investigated carefully and the War Department, guided by the Geological Survey, ought to be placed in a position to suggest the nursing of such branches of the mining industry as are essential to the provision of specific metals or minerals, for instance, nitrate. If protection by tariff is necessary to encourage the production of sundry ingredients necessary in warfare, and now lacking, then even the sincerest free-trader may well allow an exception. In this department the mining engineer is able and willing to help, as in any other.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Cyaniding Flotation Concentrate

The Editor:

Sir—In the description of the plant proposed for the cyanidation of flotation concentrate by A. E. Drucker, published in your issue of April 8, 1916, occur several statements to which I must take exception.

First, how does Mr. Drucker know that a combined hydraulic and mechanical classifier will make a sand-product with more moisture (30 to 35%) than a Dorr or Akins machine? Since the machine proposed by him exists on paper only, this figure must have been arrived at by reasoning, and it is easy to show that it is precisely the other way. The moisture in mechanically-separated sand depends on the time it is given to drain, therefore decreases reciprocally with the length and the angle of inclination of the classifier. The finer the sand, the more moisture it will retain, so that the sand delivered by a combination classifier, containing less fine material on account of the hydraulic separation in the spitzlutte, ought to be drier than the product from a straight mechanical device.

Mr. Drucker recommends the combined classifier to obtain separation at a coarser size, which is perfectly right. However, he loses sight of the fact that classification is not a separation of particles at a definite size, but that the settling velocity of a grain determines whether it will pass into the sand-product or into the overflow. Separation at a definite size can only take place with perfect homogeneous material, but not with an ore-pulp containing minerals of widely varying specific gravity. A classifier, be it hydraulic, mechanical, or a combination of both systems, necessarily delivers a sand-product with smaller heavy grains and larger light grains. In this connection, I fail to see the point in Mr. Drucker's remark on the work of a Dorr classifier at Inspiration. (M. & S. P., March 25, 1916). I am certain that if the 28.8% of *minus* 48-mesh material had to be eliminated from the feed to the mills by classification, this would result in an undesirable increase of *plus* 48-mesh sand in the overflow.

Further, I cannot at all share Mr. Drucker's dislike of elevators. The difficulties are always the result of faulty construction or lack of attention, but I agree that when a pulp is so fine as to pass 100-mesh, pumps are also satisfactory and cheaper to install. It is not true that the Frenier pump is only fit to lift to eight or ten ft.; I have pumped sandy pulp with a 54-in. Frenier to a height of 16 ft. without trouble at an elevation of over 12,000 ft. above sea-level. Inconveniences of this pump are its liability to choke with thick pulp and the irregular discharge, which in most instances necessitates the installation of an equalizer-tank with spigot through which 18 to 24 in. of height is again lost.

M. G. F. Söhnlein.

Machacamarca, Bolivia, May 10.

The Same Old Game

The Editor:

Sir—A quick turn of the wheel and we have with us again, for a long or a short stay, a condition of 'easy money,' meaning new accumulations of surplus capital and speculative symptoms. About once in each decade this epidemic of speculation sweeps over our country from coast to coast. Its presence in different parts of the country is characterized by certain concurrent symptoms, a distinct mania for buying without regard to value, on the Atlantic seaboard the mania finding expression in the desire to own 'War babies;' the Middle West has a penchant for toying with high-priced food-product issues, while farther west, especially on the Pacific Coast, the germ manifests its presence by the uncontrollable desire evinced by the patients to become the owners of a real mine, preferably a gold mine, or, failing that, they want to purchase a wild-cat of some kind.

The outbreak of this disease in any particular community is at first imperceptible, even subtle, but its presence becomes discreetly manifest in the suggestive enlargement of brokerage quarters, and a renewed thronging of our hotel lobbies with threadbare vendors of refurbished schemes. Bred from psychic mixtures of the germs of war, science, and social re-adjustments, the fever of "something for nothing" is in the blood and the leeches are ready at hand. Heaven knows where all these 'doctors' have been hibernating since 1907, but here they are with the same old methods of blood-letting at 12½ cents per share—"next week advanced to 20 cents—get in."

The dear old public is in the market, the clumsy, non-thinking, humor-lacking public, to whom surplus wealth is a detriment from which they must be promptly relieved, at least once in every ten years, otherwise there would be no development of the mass.

Well: what are we going to do about it? Do you think a word of warning will do any good? Not a bit of it! Even our most conservative bankers have thrown up

their hands in despair after futile attempts to keep the lid on these pots of rainbow gold. We, the cautious ones, stricken in a succession of similar epidemics dating from away back even to old Comstock days, may shake our worldly-wise heads doubtfully and then join in the scramble with the rest for easy money. It is a disease whose only known treatment is copious blood letting.

Recognizing the disease and the cure, why waste time in vain forebodings, but rather let us deliberate upon the ultimate benefits that certainly do accrue after the virulence of the attack has subsided and the financial pulse once more beats normally. A hundred schemes for blood-letting are conceived in the high places and the low places—the sierra and the desert, delicately whipped into shape in hotel-lobbies, clubs, and the back-rooms of real-estate and brokerage offices—and what is the result? One good money-making mine as a "shining example" for another decade at least. *Gold* mine, of course. It is *so* quick. Ten-cent stock becomes worth a dollar in a few jerks and the fever burns itself out, naturally, in spending the money. Or perhaps the 10c. stock drops to ½ cent and is removed from the board and the fever subsides, unnaturally, making an effectual cure, and carrying with it at least ten years immunity.

Mining is a great industry, our greatest, next to agriculture. Its rewards are lavish and spectacular, but spasmodic and quite likely to be lavishly expended. When all is expended one cannot go to the bank, like the farmer can, and borrow at 8% to tide him over until next year's crop comes in. That's the difference between mining and agriculture—the only difference. Failure in the one means a valueless hole in the ground and a trunk-full of worthless shares—while failure in the other means selling the farm and the Ford and starting anew.

Since the symptoms of speculative fever have a distinctive accompaniment of mania for the acquisition of possible gold mines and since the antidote is either the complete gratification of the mania or a complete blood-letting, it would seem that a system of treatment embodying a maximum of gratification and a minimum of blood-letting should be the compromise sought. Accepting these conclusions, it behooves the patient to pay some regard to the fact that a newly-discovered gold camp is not necessarily the most fruitful field for the substantial gratification of his desire. The only superior merit of a new mining district lies in the fact that it is usually easier to finance a prospect there, temporarily, at least. It becomes a fashionable centre, a resort for professional blood-letters and their fever-stricken patients. The chief disadvantage of these new camps lies in the fact that it costs more for treatment (of fever) and it costs much more to obtain meritorious mining ground, suitable for prospecting, development, and exploitation, than it does in places less advertised but equally meritorious.

Every strike of real merit generally results in the ultimate establishment, in the immediate area, of three or four persistent profitable mines. You can follow the trail of all lode mining strikes for the past thirty years and note these resultant few mines still operating in each camp, holding up their heads amid the abandoned remnants of countless mere blood-letting enterprises, Deadwood, Creede, Cripple Creek, Tonopah, Goldfield, Rawhide, Cobalt, Porcupine, and Rochester, to say nothing of lesser camps.

Since we have the fever and are going to speculate in gold mines, let us do it as rationally as possible. There is only one way to do it rationally and that is under proper guidance. If we put our money into new gold mining stocks or into un-incorporated, un-prospected, un-developed mining claims, let us be certain first of three fundamentals:

(1) That the money raised by stock-selling or private subscription is expended for prospecting, development, and operation.

(2) That some competent mining engineer has examined the projected enterprise and advanced his opinion that it is a "good gamble" at least. The best engineer in the world cannot say more than that in reference to an undeveloped piece of mining ground.

(3) That operations at the mine are superintended by experienced and honest mining men.

PERCY WILLIAMS.

San Francisco, June 8.

[We discuss the subject of this letter on our editorial page.—EDITOR.]

The Flotation Process

[The following discussion appears in the June bulletin of the Canadian Mining Institute. It refers to a paper entitled 'The Flotation Process' presented by T. A. Rickard at the 18th annual meeting of the Institute and therefore deals with the subject as presented by the same author in the MINING AND SCIENTIFIC PRESS during February and March 1916.]

G. D. VAN ARSDALE: Mr. Rickard's paper is extremely interesting and comprehensive, covering as it does the history, practical development, theory, patents, and some of the litigation of flotation. The work that I have been doing has, until recently, been confined entirely to an attempt at investigation of the theory of the subject, so that I can only comment on that portion of the paper relating to this phase. Any part of this subject is very complicated and difficult from a research standpoint and it seems to me therefore that its study may be facilitated by making, when possible, some simplifying assumptions. The most prominent feature of our modern methods is the foam or froth. Let us consider what a 'foam' or 'froth' really is. A scientific definition would be a matter of some difficulty, but for practical purposes we can consider that a 'foam' or 'froth' is really only a collection of bubbles of greater or less size or number. We can accordingly simplify matters greatly, by considering a single bubble. Now a single bubble may be roughly defined as a surface of liquid in contact with or in some

cases entirely surrounding a quantity of gas. With this definition we can make a still further simplification, which is that what we ordinarily call a liquid surface answers to a part of this definition, that is to say, it is a liquid surface in contact with a gas, and we would accordingly expect a study of particles and oils on an ordinary surface to throw considerable light on the remaining much more complicated cases of practical flotation. If then we ask why does a particle heavier than water float on water surface we can attempt to answer this as follows: If the main cause is surface tension, there should be a definite relation capable of experimental verification between the maximum size of a particle that can float, and the surface tension of the surface. It has been stated that the maximum weight that can be supported on a surface is equal to the surface tension, that is 1 sq. cm. will support 81 mg. It can easily be shown however that 1 sq. cm. will support several times this weight, so that evidently the relation is not stated. From certain surface-tension formulae, however, we can calculate the maximum sized particle of certain shapes, for example, cylinders, that will float; and experimentally with clean copper wire of various sizes the actual size that will float is close to this theoretical maximum. This proves, therefore, that we are correct in assuming surface tension as one of our main causes. Other conditions, all of which can be proved experimentally by simple experiments, are:

1. Size and specific gravity of particle
2. Shape of particle
3. Inherent quality of surface to resist wetting, and
4. Films.

It is easy to show experimentally, as we also know from practice, that some films prevent and others promote flotation, also that these films may be either a solid, a liquid, or a gas, or an electric film, that is to say, an electro-static charge. Now summing up the above, we can state that a substance specifically heavier than water may be made to float, provided the size of particle be small enough, of proper shape with respect to size and specific gravity, and provided it has a surface film sufficient to prevent wetting, which film may be either a solid, a liquid, a gas, or an electro-static charge or a combination of these. You at once see that this statement is very close to a similar statement as to the conditions producing colloids, and the study of colloids as applied to flotation will, therefore, doubtless clear up the subject considerably. The main conclusion we have reached in the application of the above to the more complicated cases of actual flotation practice, is that surface tensions and the resultant of these which determines wetness or non-wetness of particles is the 'how' of flotation or, in other words, the immediate cause or mechanism of the results, and that the study of colloids and electro-statics will furnish the 'why' or the ultimate cause. Electro-statics will probably act as one of the explanations of wetness or non-wetness, and also possibly as one of the explanations for the attachment of films. The study of flotation oils at first glance also seems hopeless in view of the number of these and the number of possible combinations, but we can also simplify this very much if we consider them from the standpoint of their functions.

Their main functions are evidently two:

1. To furnish a non-wet film on the particle
2. To furnish a froth by reducing the surface tension.

This at once gives us a classification of oils into two kinds with respect to these functions—

1. Oilers
2. Foamers

and by taking into account also the inter-action of physical qualities of one on the other in a mixture, we can have a somewhat rational basis for their study.

What we apparently have not so far obtained and need very much is a definite understanding and statement of the specific physical qualities of the oils themselves that they need to enable them to fulfill these functions and as a result of this a rational and scientific method of testing for their selection and use.

Alfred Stansfield: In reference to the study of soap bubbles and their relation to flotation I have never been able to rid myself of the idea that the reason soap bubbles stick together is because of the stickiness of them.

H. W. Du Bois: I also should like to express my appreciation of the value of Mr. Rickard's paper, and of the admirable manner in which he has presented the facts. The phenomena of flotation are apparently so simple that until quite recently investigation in this direction has been disregarded. It may, perhaps, be noted that whereas according to Biblical teaching the spreading of oil on water is supposed to cause its troubling to cease, in the case of flotation oil is a chief source of trouble. While one or two statements made by Mr. Rickard appear to me to be contradictory, he has succeeded in his paper in presenting the whole matter in a very clear and understandable fashion, which in view of the befuddlement caused in the past by the writings of partisan experts, represents a distinct service to the profession. Hoover, in the first edition of his book on flotation published in 1911-12, stated that it was impossible to treat by this process ores containing chalcocite or bornite. Chalcocite, however, is readily floatable; although bornite presents a more difficult problem, for bornite is invariably accompanied by a surface film, ordinarily considered now to be limonite, and this prevents the oil from coming into contact with the mineral particle. In an attempt to overcome the film effect on their oxidized ores, the Braden Copper Company started introducing the oil during the crushing period, so that a more intimate contact was obtained while the mineral surfaces were fresh. They found that it was possible to greatly increase the recovery in this way on all ores containing oxides or minerals with drusy surfaces, but recovery is by no means good even yet. When the feed is low-grade the loss due to the content of bornite is not important, but when high, as it is in the Alaskan mills (sometimes 20%), it is most important. The first attempt to overcome the effect

of this limonite film on the Alaskan bornite ores was a repetition of Braden's more or less successful work—that is, by means of fine crushing. But in the present instance this was a failure. It is, of course, possible to remove this 'film' by using sulphuric acid, but in an isolated region like Alaska the high cost of acid makes its use prohibitive. The difficulty of the problem led to a closer study of the 'reason' for flotation, and the electro-static theory seems to be the best explanation of the problem. Assuming this theory to be correct, then we can say that in flotation we have a system in which the mineral particles are positively charged and the gangue negatively. The oil particles are negatively charged, and so adhere to or 'wet' the mineral particles and repel or do not 'wet' the gangue particles. If then we consider that for some reason bornite is negatively charged, we have at once an adequate explanation of the fact that bornite has been unfloatable. Some work has been done along this line, and it has been found that by treating bornite to the fuming action of nitric acid, it is then readily floatable. This is simply a change of polarity due to high temperature, the negatively charged bornite becomes positively charged and is immediately 'wetted' by the oil and floats. It is hoped that a further study along lines suggested by the electro-static theory will yield important commercial results. I may add that a number of companies take care to regulate the feed to the flotation unit and keep it low in order to get high extraction. This possibly is correct, but their experience with high-grade ores has been that this is entirely unnecessary.

A Volunteer Engineer Corps

The Editor:

Sir—Following our conversation over the telephone, you will be interested in knowing that after a conference with Capt. Park, Col. Perkins, Col. Swift, and the Adjutant-General's office of the State of California, I have decided to recruit a battalion of engineers for use in the present emergency. I intend recruiting this battalion from all portions of the State, one company headquarters to be located in San Francisco, another in Oakland or Berkeley, and a third at Los Angeles.

There are no volunteer engineer troops west of Golden, Colorado, and not nearly enough to supplement such troops as are at present mobilized, so that it is quite certain when this battalion is recruited to its full strength, that it will see service. I am taking the necessary steps to have engineers added to the California quota, as these troops will be certainly needed to properly take care of the castrametation of the present mobilization. Provisional headquarters are at the office of the Pelton Water Wheel Co., where I can be reached at any time.

As this battalion is the first of the engineers, outside the National Guard, to offer its services to the War Department, the probability of its being accepted is very high. The San Francisco company will be organized tonight, the Trans-Bay company will be organized tomorrow night, and the Los Angeles company within the next two or three days. Persons in the South desiring information regarding the Company can secure it from Charles T. Leeds, Central Bldg., Los Angeles.

I trust that you will be able to find space for this in your columns.

J. W. Swaren.

San Francisco, June 19.

The Mexican Silver Dollar

The Editor:

Sir—Referring to the last paragraph on page 774 of your issue of May 27, 1916: *The Economist* is in error regarding the Mexican silver dollar. The Mexican gold dollar is worth approximately 49.8 cents U. S. or a little less, depending on the amount of service and consequent loss in weight the pieces have undergone. The old-style Mexican silver peso, commonly called "*peso fuerte*" weighs, when new, 27.073 grams and contains 0.9027 silver or 24.4 grams. The tolerance in fineness being plus or minus 0.002 and the tolerance in weight, plus or minus one gram. Of several 100 lots of used *pesos fuertes* weighed, the average weight of this coin in circulation is 27 grams, with negligible variation. The silver content of 24.4 grams or 0.785 oz. troy is worth 50c. U. S. when silver is worth 63.7 cents per ounce. Under normal conditions this silver peso, with liberty cap on one side and eagle on the other, is worth approximately 50 cents U. S. regardless of the price of silver. At present it must be classed as unrefined silver bullion.

The fractional silver coins are of less weight and contain less silver. The 50-centavo pieces, *tostones,* weigh (actual average of several P100 lots) 24.8 grams per pair and are 800 fine; the silver per peso being 19.8 grams or 0.636 oz. troy. They are worth 81% of the silver peso for their silver contents.

R. S. Burdette.

Guadalajara, June 9.

Spain is said to be beginning an industrial growth of importance. The Spanish people, who have neglected the economic development of their country's natural resources for generations, are turning their attention to water-powers, mineral deposits, and manufacturing. This is a direct result of the loss of their colonies in the Spanish-American war, which made it necessary to look at home for opportunity rather than seek it in the West Indies or the Philippines. As is well-known, Spain has an important mineral output of lead, copper, iron, quicksilver, and sulphur. Barcelona, the chief industrial centre, is a seaport of 750,000 people on the Mediterranean Sea. It is possible that some of the Americans who are learning Spanish with the intention of using that language in Latin-American countries, may become engaged in operations in Spain.

Hammer-drills were originally only of one type, stoper-drills for up-holes. Now there are also mounted hammer-drills and sinkers.

Fire Insurance on Mining Property

By Charles T. Hutchinson

PREFACE. Everybody nowadays takes out fire-insurance on whatever he may possess that is subject to fire risk. It is the thing to do. The conventional procedure is somewhat like this: The prospective insured has a friend, a son, or a nephew; or some friend or director of his company has a friend, a son, or a nephew who is in the fire-insurance business. What could be more natural, therefore, than to give John, Mike, or Bill your fire-insurance, because, forsooth, he is a good fellow and can play a good hand at auction?

When the policies arrive, they are turned over to the cashier or book-keeper who chucks them in the safe, pays the bill, and then forgets all about the transaction—unless there should be a fire. Then all is changed. If the fire-proof safe has by some lucky chance escaped destruction, the insurance policies at once become objects of consuming (if not consumed, of course) interest. They are rescued from their comfortable pigeon-hole and carefully scrutinized, and not infrequently produce a series of shocks when the insured finds out that the nature or cause of his loss is not covered, that the gross amount of the insurance carried is insufficient, that the insurance is not distributed in accordance with the relative liability to fire damage of the classes of property insured, or that there is a co-insurance clause whereby the insured shares the risk with the company.

The cardinal point that everyone should realize and then take to heart is this: that after a fire the burden of proof rests upon the insured. The insurance companies are all, *ex-officio*, Missourians; they require to be shown, and the law sustains them in this position. Every claim as to what was destroyed and what it was worth at the time of the fire must be set forth in detail and substantiated in a manner satisfactory to the insurance company. The time to prepare for realizing upon a fire-loss is before the fire, not afterward, so a few business-like expedients in the interest of preparedness may save thousands of dollars.

INVENTORY. Everybody, individually or collectively, should take a physical inventory once a year of the property insured. This inventory should be prepared in detail, setting forth every item, its value and location in the building where it is stored or erected. The building itself should be inventoried in sufficient detail as to type of construction, quantity and cost of material used, labor-cost for erection, in detail, if possible, as to sub-contracts let for such items as foundations, plastering, installation of lighting and plumbing equipment, and other items. Foundations for the building proper as well as lighting fixtures and plumbing are regarded by the insurance companies as part of the building, and therefore may not be classed as machinery or plant-equipment. Prepare the inventory in duplicate; keep one copy within the building, if you like, but send another copy to the nearest safe-deposit vault. All office-safes and vaults are not fire-proof; many of them are far from it, as the San Francisco fire showed.

DEPRECIATION. This is an item upon which experts as well as insurance companies differ. Adjusters look askance upon a plant or factory that was shut-down at the time of a fire. So many attempts have been made to sell idle plants to insurance companies through the medium of a fire, that even the honest loss is subject to the most careful scrutiny and investigation. The rate of depreciation imposed by an insurance appraiser for an idle plant is necessarily much greater than for one that had been operating continuously; in some cases it has been placed as high as 25 to 50% per annum. Such amounts as have been written off on the inventory for depreciation should be clearly shown thereon, and all copies of inventories for previous years should be kept as a matter of record in order to show the total depreciation over the period of the plant's existence.

SALVAGE. After a fire, clear away the débris as quickly as possible, provided, of course that the plant is to be re-built. Do not destroy the remains of any piece of machinery until the loss has been adjusted. If a man may be identified by his thumb-prints, so in turn may the presence of a crusher be proved by a warped and twisted shaft, although the rest of it may be unrecognizable. The insurance adjuster or appraiser is expected to check the inventory as best he can by inspecting the débris, so anything that the insured can do to facilitate the work is not only appreciated by the company but hastens a settlement. Keep track of your labor-cost for salving wreckage, as allowance will be made by the company for this item, although, of course, the total award cannot exceed the amount of insurance carried. Total losses are the exception, however, especially where machinery or any kind of plant or factory-equipment is involved.

ADJUSTMENT. After the fire, notify the insurance company—the sooner the better. The adjuster will soon put in an appearance, make an inquiry to determine the cause of the fire, and size up the situation generally. If the loss involves the destruction of property of a technical nature, he will call for an appraisal. Two appraisers will then be appointed, one to represent the insurance company, and one the insured. These two, in turn, will agree upon an umpire to settle any points upon which they cannot agree. This done, the appraisers will at once call upon the insured for a copy of their inventory, which, alas, in most cases, does not exist. In the absence of an inventory, the appraisers,

working together, must do the best they can, by examining such records, invoice files or other office data as may not have been destroyed by the fire, to prepare some kind of a list as a basis to making the appraisal and then a proof of loss. In case all records have been destroyed in the fire, verbal testimony from employees is taken from which a rough inventory is prepared. All of these expedients involve much time, expense, and labor, adding enormously to the difficulty of realizing upon the actual loss sustained. The burden of proof rests with the insured. The insurance company must be shown.

Appraisal. The general form upon which an appraiser's report is made is as follows:

Item	Description	Installed-Cost	Sound-Value	Loss
1	Concentrator	$575	$500	$125

In explanation, the installed cost includes:

Factory cost of the concentrator.
Transportation from factory to plant-site.
Cost of erection.
Cost of foundations.

The sound-value is the same as the installed-cost, less whatever allowance is made for depreciation, in other words, the value just before the fire. The loss-item is self-explanatory. The above example indicates that the concentrator was not a total loss, and salvage appraised at $75 was recovered. The starting point in any appraisal is the installed-cost, which emphasizes the necessity for a complete inventory as a means whereby the sound-value may be established and the insurance recovered.

Co-Insurance. Many people who take out insurance are attracted by the lower rates made for policies having a co-insurance clause, and authorize its insertion without understanding fully what it really means. In general terms, co-insurance signifies that the insured shares the risk with the insurance company. The property is assumed to be insured for its full sound-value; the difference between the full value and the amount of insurance placed with the company is the part of the risk assumed by the insured. Here is the way this actually works out: If property is insured for $20,000 and is determined to have been worth $60,000 at the time of the fire, and if there has been a 33⅓%-loss, the insured gleefully expects to recover from the insurance company one-third of $60,000, or $20,000, the total face-amount of his policies. Not so, however. All he can recover is one-third of $20,000, which is a very different story. By reason of the co-insurance clause, the insured assumes the risk for whatever difference there may be between the insurance placed with the company and the actual value of the property insured, in this case $60,000 less $20,000, or $40,000, in other words, the insured has assumed two-thirds of the risk and the company one-third, and whatever loss may occur is settled in this proportion.

Salesmen of all kinds understand the psychology of the printed word. The average man, when offered for his consideration a printed document of any kind, whether it be a lease, contract, insurance policy, or what not, will glance over it hastily, and if the price is right, sign it. If on the other hand, there are any riders attached, either type-written or otherwise, they will receive his careful scrutiny, while the printed portion will escape his notice. There is an air of finality about print, somehow, that, in itself conveys the impression that it cannot be changed. It suggests the idea of an ultimatum —the last word. That is why few men read their policies carefully, until after a fire; therefore read your policies, study them, and know where you stand beforehand, rather than afterward.

Selecting an insurance broker to handle such matters is or rather ought to be done on the same basis as any other kind of business. The broker is an advocate for the insured, and stands between him and the insurance company. If the broker knows his business, he can save money, and infinite trouble in case of a loss, as well as see that the policies adequately protect the interests of the insured. The careless haphazard way in which most men dispose of their insurance business, as they would a donation to the old ladies' home, is anything but intelligent. Relatives or friends of managers, directors, or others in authority may be and often are excellent fellows, but, this fact, as such, is hardly sufficient reason for their being entrusted with so important a business matter. Select your insurance broker as you would your doctor, lawyer, or engineer, and it will pay you well; and in the meantime remember that preparedness may be applied in many senses other than military. In other words, don't forget the inventory.

Domestic fluorspar mined and marketed in the United States in 1915 amounted to 136,941 short tons, valued at $764,475, compared with 95,116 tons, and $570,041 in 1914. Compared with the next highest year, 1912, the output last year represents an increase, according to the U. S. Geological Survey, of more than 20,000 tons, or nearly 18%. As usual, the bulk of the fluorspar produced was sold as gravel-spar, the quantity in 1915 amounting to 114,151 short tons, or 83% of the total. Sales of fluorspar in 1915 were reported from five states —Illinois, Kentucky, New Hampshire, New Mexico, and Colorado. All showed increases over 1914 except Colorado, where there was a large proportional decrease. The large amount of fluorspar sold in 1915 may be accounted for principally because of the great demand for steel. It is estimated that about 80% of the American fluorspar output, mainly in the form of gravel-spar, is consumed in the manufacture of basic open-hearth steel.

Zinc ores are being imported into the United States from Sardinia, Spain, Australia, and Africa. This is a direct result of the War and the consequent demoralization of the zinc-smelting industry in Belgium and Germany. While the import of zinc ore from most of these countries will likely cease when the War is over, some of the new relations may be continued. Similar departures will probably be effected in other industries, the initiative having been supplied by the War.

HAYWARD'S COTTAGE. THE TOWN OF SUTTER CREEK.

The Re-Opening of Old Mines Along the Mother Lode, California

By T. A. Rickard

A few days ago[1] I stood with Mr. T. Walter Beam on the hillside above the little settlement of Sutter Creek, in Amador county, California, and saw the first steps taken toward the re-opening of an old and famous mine, variously known as the Eureka, the Amador, Hayward's, and the Hetty Green mine. It was a fascinating quest on which Mr. Beam had started and the heavens seemed to smile on his endeavors. At this time of the year the foothills are carpeted green and the oaken glades give the landscape a park-like beauty suggesting human design. The hillside on which we stood, torn long ago by mining operations and seared formerly with roads, was now a verdant slope, showing one white outcrop of quartz amid several clumps of trees growing out of the open-cuts made by an earlier generation of miners. Two or three black dumps, partly overgrown with grass, looked like culm heaps, for the black slate characteristic of the Mother Lode at a distance resembles the carbonaceous shale accompanying coal. The line of the lode could be traced northward by these dumps; among the houses of Sutter Creek it was easy to pick out the Wildman mill and shaft-house; beyond it were the Mahoney mine-buildings, and near the top of the ridge on the farther side of the village were the Lincoln shaft-house and a big red open-cut that cleft the ridge right to the sky-line. These three mines are now idle, but from behind us, southward, came the muffled roar of the Central Eureka mill and over the ridges both north and south there was, we knew, a succession of busily productive mines and mills. The village itself, nestling among the gentle hillsides, looked idyllic, the tall poplars giving the little houses a quaint dignity, which the warm sunshine mellowed into quiet beauty. Sutter Creek is too much of a mining settlement to be altogether admirable on near acquaintance, but viewed from a distance it vibrates with the afterglow of that romance which Bret Harte has crystallized for us in imperishable writing.

The Eureka mine has been closed-down since 1886—just 30 years ago. It was located in 1852, which is also the year in which the first lode-claim was staked in Amador county. A 10-stamp mill was built on the Eureka in 1852, and a new mill of 20 stamps was erected in 1856, with 20 more in 1857. The next claim southward, the Badger, was located at the same time and a 10-stamp mill was built upon it in 1854, with 6 more stamps in 1857. Alvinza Hayward, the hero of the story, acquired a controlling interest in the Badger claim in 1854; he purchased the Eureka in 1858, and became sole owner of the Badger in 1859.

Writing in 1868, J. Ross Browne[2] gives the length of the two consolidated claims as 1800 ft.; he states that the average width of the vein is 12 ft. and the dip 75° east. The hanging is stated to be "hard serpentine," while "the foot is slate, polished and smooth." We must not smile at the petrography of these early writers, who had no microscopes, but most of us know now that the hanging of the Eureka vein is diabase and the footwall schist. According to the same chronicler, the mine then exposed only one ore-shoot, which was 500 ft. long at the surface and 600 ft. long on the 1200-ft. level.

[1] This was written at the end of March. Difficulty in obtaining accurate information concerning the events of 40 years ago explains the delay in publication.

[2] 'Resources of the Pacific Slope.' J. Ross Browne, 1869.

"The walls come together," he says, "at the ends of the pay chimney, which dips to the north at an angle of about 80°." Thus the orebody pitched northward at nearly the same angle as the vein dipped eastward. In an earlier report, made in 1867, Ross Browne says: "The quartz vein is in places almost a powder and is mixed with slate and clay. The length of the ground worked is about 160 yards, and both north and south the vein seems almost to disappear." Such sugary or crushed quartz is not uncommon on the Mother Lode; the pinching at the end of short ore-shoots gives them a lenticular shape in horizontal section. At an earlier date J. D. Whitney said: "The vein is enclosed in a dark colored, rather soft, argillaceous slate. In the Eureka the mass of veinstone is from 8 to 20 ft. wide, but in the Badger it widens out suddenly to 40 ft. The length of ground worked out in both mines is about 470 ft.; so that the body of quartz is very short in proportion to its great width, being almost a column, or chimney, rather than a vein." The deepest incline—for the shaft was sunk on the vein—was 1230 ft., of which it is recorded that it was then "the greatest depth reached in the mines of California." At that time the two mills, aggregating 66 stamps, were kept busily employed, for the supply of ore was so plentiful that some of it had to be sent to custom-mills in the valley below. Thus, the Eureka must have been highly prosperous at the period of this report by J. Ross Browne, the distinguished father of a distinguished son, Ross E. Browne, as well known in South Africa as in California. The elder authority states that "within 500 ft. of the surface the average yield did not exceed $10 or $11 per ton, and now it is, according to report, $27, with a wide vein and 125,000 tons of ore in sight—enough to keep the two mills going for five years." The total yield up to that date—1867—was said to have been $6,000,000. Like many old and abandoned mines, the Eureka has been credited with a fabulous production. Writing in 1869, Dr. Raymond said that popular rumor concerning a profit of $50,000 monthly was possibly true at one time. The total yield up to 1866 was estimated by Ross E. Browne at $6,000,000. Allowing $1,500,000 for 1866, 1867, and 1868, and taking the figures given elsewhere in this article for the subsequent years until 1875, with a guess at the yield up to 1879, I estimate the total production at about $12,000,000.

In 1868 Rossiter W. Raymond succeeded J. Ross Browne as Commissioner of Mining Statistics and in his annual reports from 1869 to 1875 I have found a number of references to the Amador mine, as it was called then. In the first report the depth of the shaft is given as 1054 ft. vertically and 1109 on the incline, according to a new survey. Water was hoisted in buckets, the method known as 'bailing.' "This plan" says Dr. Raymond "was adopted and obstinately adhered to by Mr. Hayward, as long as he owned and managed the Eureka."

Between 1868 and 1872 the mine had its ups and downs. At the end of 1868 rich ore was struck and large reserves developed. The depth of the Eureka shaft was deepened to 1350 ft. The Badger shaft also passed through rich ore. In 1869 the mine produced $656,326 in gold and paid $384,800 in dividends, from 32,510 tons that yielded $20.19 per ton. The cost of mining is given as $4.68 and of milling $1.97, making a total of $6.65. On April 15, 1870, a fire caused a suspension of work for four months. During that year the yield was $301,533 and dividends $111,000. In the report for 1871 it is stated that the dividends were only $24,000, as against $155,100 in 1870, indicating that $11,500 must have been distributed after the report for 1870 was closed. The repairs and erection of a new hoist after the fire appear to have taken nearly twelve months, the delay being due partly to a virulent miners' strike during the summer of 1870. In the new equipment, the old bucket was replaced by a cage holding a car of 1800 lb. capacity. Drainage was effected by iron tanks, one of which is to be seen on the hillside today, somewhat battered by the exploding of dynamite by boys on the occasion of the recent celebration of the re-opening of the old mine. In 1871 only 17,790 tons was hoisted and 16,490 tons milled for a yield of $201,357, equal to $12.21 per ton. Colonel John D. Fry was president; he was one of the founders of the California Safe Deposit & Trust Co., he operated mines at Grass Valley, and in 1881 it was he who sent John Treadwell to Juneau and thus became one of the first owners of the Alaska Treadwell. David D. Colton was treasurer of the Central Pacific Railway, and it was through his influence probably that the branch line from Sacramento to Latrobe was built in 1869. Latrobe is 18 miles from Sutter Creek; the freight by wagon was $12 per ton at that time, and the freight from San Francisco to Sacramento was $5.50 per ton.

Alvinza Hayward owned the mine for about 14 years, from 1854 to 1868. Raymond's reference to Hayward's obstinacy in regard to the use of buckets for draining the mine, "as long as he [Hayward] owned and managed the Eureka" suggests that he did *not* own it at the time, late in 1868, when Raymond wrote this. Up to 1865 he had a partner named Oscar L. Chamberlain. On March 1, 1868, Hayward & Co. sold out to the Amador Company for $750,000. Concerning the sale of the mine in 1868, Raymond said in 1869: "The dividends were $6 per share monthly, or 18% annually on the capital stock, yet the mine was sold at $200 per share. This is a fact which Eastern capitalists would do well to ponder. In the San Francisco market, where the value of mines is best understood, the stock of an active successful mine is not intrinsically worth par unless it is paying 30 to 40% annually." The property, which included the Eureka and Badger claims, with the mills, was examined for the purchasers by William Ashburner and Henry Janin, who computed the total reserves at 108,027 tons, having a gross value of $1,778,336. "The cost of mining and milling," says Raymond,[3] "does not exceed $6, leaving an apparent profit of $1,130,204." But a deduction of 25% was made for contingencies, over-estimate, etc., so

ONE OF THE EUREKA DUMPS.

A REMNANT OF AN OLD HOIST.

that the net value was reduced to $847,653. The average yield in 1868 is given as $21.77, the dividends being $7 per share monthly on 37,000 shares. The output was 1800 to 2200 tons per month. A longitudinal section of the mine by Augustus J. Bowie, later famous as the authority on hydraulic mining, is given in the report of 1869. It shows the property covering 1850 ft. on the vein, which is given a dip of 71°, the width of quartz ranging from 3 to 20 ft. At that time it was 15 ft. wide in the lower stopes.

Hayward sold out to a group of whom Michael Reese was the principal operator. Others were Milton S. Latham, David D. Colton, and John D. Fry. Hayward was a friend of some of these men and he came to Sutter Creek occasionally, for he had other mining property in the county—at Plymouth, for example—but I believe that he did not control the Eureka after 1868. In Raymond's report for 1872, it is stated that the Amador, better known as the Hayward mine, "has been disincorporated preparatory to its transfer to English purchasers." Transfer from the Amador to the Consolidated Amador Company was completed in November 1872. The new consolidation included the Wolverine (or Maxwell) and Railroad properties, both previously owned by incorporated companies. The 'Wolverine,' had been bought by John W. C. Maxwell in 1867, as he himself has informed me. Previously Hayward had done some work, attracted by the prominent outcrop on this claim, but he abandoned it; later D. O. Mills and his brother Edgar took an option on it for two years but did no work. At the expiration of that option Mr. Maxwell bought it, for $5000 in cash, in 1867, as already stated. Shortly afterward Milton S. Latham, D. D. Colton, and General E. D. Keyes[4] acquired interests with Mr. Maxwell and, at their request, he organized the Maxwell Mining Co. At that time also John A. Steinberger, who became the superintendent, was given a 1/20 interest by Mr. Maxwell. He sank the shaft and opened up the vein in depth, down to 125 ft. In 1870 Mr. Maxwell sold his remaining interest to the group that had purchased the Hayward property, namely, Latham, Colton, and Green. Latham was managing-director and Green a director of the London & San Francisco Bank. It was understood that Green would consolidate the adjacent properties with a view to placing them on the London market.[5] Thus Green comes into the story. Edward H. Green hailed from New Bedford (Massachusetts), where also he married Hetty Robinson, who inherited wealth from her father, a local merchant. He had made money in the whaling business and in Manila hemp; he was in the shipping trade in a large way and made frequent journeys to London and the Orient. On one of these journeys he met Hayward and Colton at San Francisco. Hearing them talk about gold mining, he came up with them to Sutter Creek to see the Eureka. He became keenly interested and on his next visit to London he got several of his English friends to join him in buying the property. In this deal Hayward acted merely as introducer and promoter, he had been out of the mine for four years. Leland Stanford was in the deal with Green and became a director in Green's company, the Amador Consolidated.

The levels in the mine were named after the various stations on the way to New York. Thus the 700-ft. level was the Latrobe; the 800 was called the Folsom; then followed the Sacramento, San Francisco, Panama, and New York levels. After 1872 the lower levels were named after the directors: Green, Latham, De Laski, and Colton. Later the geographical nomenclature was resumed, and the levels become successively the London, China, and Paris.

In January 1872 Steinberger, the superintendent, reported that the vein was looking most promising in the lower workings, on the Green and New York levels. In the report for 1873 the output from December 1, 1872, to January 31, 1874, (14 months) is given.[6] showing

[4]The father of the late W. S. Keyes.

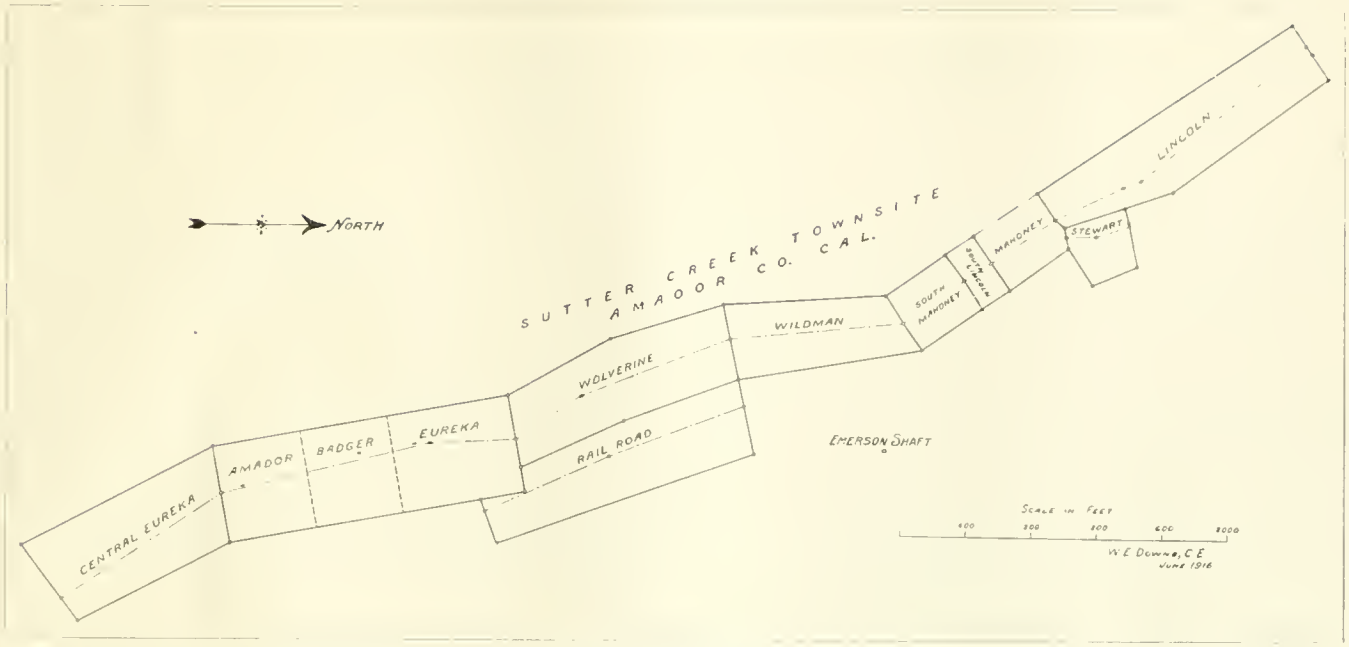
[5]For these notes I am indebted to Mr. Maxwell.

[6]The Amador Consolidated company operated the mine as from December 1, 1872, hence the irregular period.

22,160 tons crushed, yielding $102,294, or $17.91 per ton. In addition, $1953 was received on bullion produced, this may have been the yield from specimen ore. Dividends for the period were $180,000. The North shaft had been deepened to 1873 ft. The vein had narrowed from 25 ft. on the Colton level (1125 ft. vertical) to 1 ft. at the bottom of the shaft (90 ft. deeper), but the ore was richer. "From the Colton level the vein shows much confusion," says Superintendent Steinberger. Sudden pinchings and widenings had bothered him. In 1875 the same superintendent reports for the 14 months ending on April 1, 1875, namely, from February 1, 1874, so that this connects with the previous accounting. A new level below the Colton shows a decided improvement. The North shaft has been sunk 220 ft., but there is still "much confusion" in the vein; the hanging wall is broken, the quartz is small and "much mixed with slate and granite" (meaning diabase). During this period 22,098 tons had been milled for a yield of $239,717, or $10.84 per ton. The 'sulphuret' account showed $20,254 from 219 tons, or $92.27 per ton of concentrate. The total receipts were $270,014. Dividends $30,000. On December 20, 1875, a fire, supposed to be of incendiary origin, started in the middle shaft. On November 24 of that year the secretary reported "two feet of good rock" in the bottom of the main shaft, which was then 2063 ft. on the incline or 300 ft. deeper than the Paris level. These lower workings have never been seen since then, for nobody penetrated below the 800-ft. level after the fire of 1875. The workings were drowned and the mine was re-opened subsequently down to the 800; desultory work continued and stopped finally in 1878. This refers to the Eureka mine. All other operations also ceased for a year or so; then some work was done at the north end in the Wolverine ground, the shaft being sunk from 600 to 1500 ft. in 1879. From the bottom a drift was started southward to tap the old mine, but there was much trouble with water, and there were other difficulties. Several years were spent in unproductive operations. In 1886 Green came to Sutter Creek, and with him Hayward; the two of them had a carousal, followed next day by a consultation at the mine. It was then decided to close-down, with the intention, at some future date, to re-open and re-equip the old Eureka workings. Assessments had been levied from 1881 to 1885, with the result that 12,000 shares were forfeited, leaving the remaining 18,000 shares in the hands of Green. All the records of the company, save a few letter-books at Sutter Creek, were destroyed in the San Francisco fire.

From Green the property passed to his widow, Mrs. Hetty Robinson Green, who refused either to operate the mine or to sell it until late last year, when, on the initiative of Mr. Beam, a syndicate was formed to acquire the property at a price a little over $500,000 in cash. In 1894, while examining a mine in the adjacent district of Volcano, Mr. Beam's attention was attracted to the Eureka mine by the local talk concerning it. He was informed that all efforts to get a bond on it had been 'turned down' by Mrs. Green. In 1912, while on a second visit to Sutter Creek, he collected what information was available and decided to recommend his friends to approach the old lady at New York. But she proved refractory, declining to talk business. Six months later while Mr. Beam was in New York, he managed finally to get an appointment with her son, Colonel Green (he had been on the staff of a State Governor), and on that occasion he learned that Mrs. Green had kept the property in case her son should care, at any time, to re-open it on his own account. Three years elapsed—bringing the date to 1915—before the negotiations were concluded, Mrs. Green finally consenting to take payment in spot cash when the Colonel had indicated clearly that he had no desire to go into mining. However, she insisted on a laborious inquiry being made to ascertain if any of the heirs of the friends of her deceased husband had any claims on the property, that is, those whose stock had been forfeited for non-payment of assessments during the long interval since work had ceased at the mine. The story is interesting as illustrating Mr. Beam's persistence in his purpose, which he is now in a position to fulfil. On January 10, 1916, the transfer was finally executed in San Francisco and on February 24 the event was celebrated by the people of Sutter Creek in appropriate fashion. The inscription "So long Hetty" on one of the banners, paraphrasing a vaudeville song, served to express the gratification of the local people in seeing an absentee owner transfer an idle property to men able and willing to exploit it once more. The new operators include a group of men notable in mining. The president of the resuscitated Consolidated Amador Mining Company is William D. Thornton; John B. Farish is a director; among the principal shareholders are Thomas F. Cole, John D. Ryan, Chester A. Congdon, William E. Corey, James Hoatson, Ambrose Monell, William W. Mein, and Philip L. Foster. "None of these need any introduction. They are experienced men, well aware of the risk incurred in paying a large sum of money for a mine full of water, but they have justifiable confidence in the prospect of more than recouping themselves.

Alvinza Hayward has passed into local history as a courageous prospector who stuck to an unproductive claim until it developed into a rich mine. In Amador county you hear of the storekeeper who refused him a sack of flour and of another who helped him and was pensioned when Hayward became a millionaire. It is a fact that he sank the Badger shaft to 700 ft. before he struck rich ore, persisting with a miner-like tenacity of purpose until his cash and credit alike were gone. Some of his men stuck to him so that he succeeded at last in getting to the ore, which, without scientific evidence, he confidently expected to find. At that time Chamberlain, a merchant in San Francisco, gave him credit and that is how the latter became a part owner, a partner, and subsequently rich, when the mine developed into a bonanza. Hayward is also credited with great knowledge of mining and unusual sagacity in the development of mines. Much of this is untrue. Alvinza Hayward came from the northern part of New York state; he was trained in

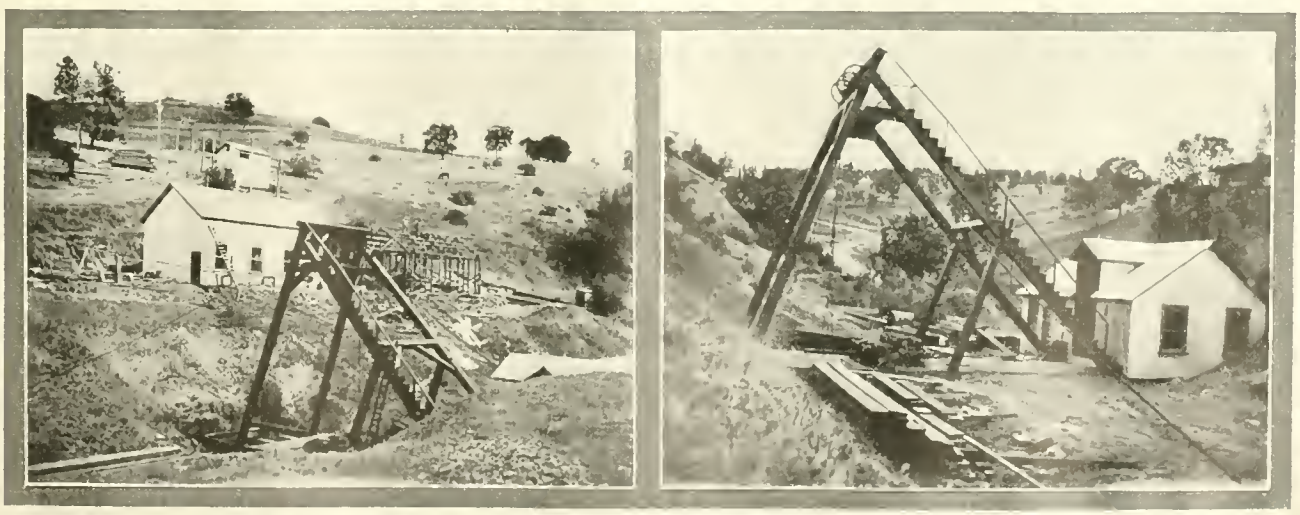


THE CLAIMS SOUTH OF THE WILDMAN UP TO THE CENTRAL EUREKA BELONG TO THE AMADOR CONSOLIDATED. THOSE NORTHWARD, INCLUDING THE WILDMAN, TO THE LINCOLN CONSOLIDATED COMPANY.

an Eastern law-school; he was a well educated and extraordinarily shrewd man; he made a lot of money in mining by intelligence, luck, and clever dealing. One characteristic story is that of the Empire and Pacific mines, now constituting the Plymouth Consolidated. When Hayward owned the control of the Empire he followed the ore-shoot where it pitched into the Pacific ground and extracted ore to which he had no right. Later, he bought the Pacific claim for himself, sold his holding in the Empire, and thereupon brought suit against the latter for trespass, on the basis of the ore removed by himself formerly. He obtained judgment, and the Empire company being then impoverished, he got that claim by default. He was a speculator and promoter, not a mining engineer. Although shrewd, he was a victim to occultism, and used to take the advice of spiritualists. For instance, it is a fact that he spent $70,000 in erecting a furnace and otherwise equipping a quicksilver mine, near Livermore, that never yielded a single flask of quicksilver, although, guided by the 'spirits' he bought 2000 flasks so as to be prepared for a large production.

Hayward is credited popularly with having made $5,000,000 out of the Eureka; it is more likely that this amount represents the gross yield during the time he operated the mine and that his profit was about $2,000,000. His fortune was increased by operations on the Comstock, the Utica mine at Angels, and by other ventures. He died in San Francisco on February 14, 1904, being then 82 years of age. He is still remembered gratefully by many old people at Sutter Creek for the personal kindness and financial help that he gave them when they were 'hard up.' Let that be his epitaph.

A SHAFT-SINKING record has been established at a mine on the Gogebic range in Michigan. The remarkable distance of 190 ft. was sunk in one month. This includes lining of the shaft with steel.



RE-OPENING OF THE EUREKA MAIN SHAFT, SHOWING TEMPORARY HEAD-FRAME.

Cobalt: Its Possible Uses

By F. H. Mason

THE average man is apt to associate cobalt with only a series of beautiful blue pigments. Of course, everyone knows that cobalt is a metal, in the same way that one knows that lithium, strontium, calcium, and many other elements rarely seen in the metallic state, are metals, but that it can serve any useful purpose other than in the manufacture of 'smalt' does not, as a rule, enter one's head. Not only does the supply of cobalt oxide produced in Canada each year greatly exceed the demand, but a large quantity of perfectly good cobalt ore goes to waste, after the silver content has been removed. Therefore the Mines Branch of the Canadian Department of Mines determined to demonstrate its own usefulness by finding a use for this surplus supply.

Both chemically and physically cobalt is closely allied to nickel. It has the same atomic weight, forms a similar series of salts, is dissolved and in many cases precipitated by the same reagents, and, like nickel, is not easily corroded; both metals have about the same specific gravity, nearly the same high melting-point, are white, and hard and capable of taking an extremely high polish that is not readily scratched. Naturally, then, the research of the Mines Branch fell into the line of investigating whether cobalt could not be substituted for nickel in some branch of industry in which the latter metal is employed. To tell how well it has succeeded up to date—the research is still being prosecuted—is the object of this article.

The principal use for nickel in the arts is to give a protective coating, electrically deposited, that not only greatly retards corrosion but also, in many instances, gives an infinitely better appearance to the article so treated. As long ago as 1878 A. Gaiffe* stated that cobalt could be deposited electrolytically from solutions of its double sulphate with ammonium, that the deposit was harder, more beautiful, and adhered more tenaciously to the article plated than deposits from the corresponding nickel salt; but, to get these results it was necessary to use a weak current. In those days cobalt was a rarity, and the matter appears to have escaped serious attention until the Mines Branch took it up again, with the object already stated. The investigation into the possibilities of using cobalt instead of nickel for protective plating, which forms only a part of the research, has been thorough, and the results have been published in a pamphlet entitled 'Electro-Plating with Cobalt,' which can be obtained from the Mines Branch of the Department of Mines, at Ottawa, and to which those interested in the subject are referred for more minute detail. A considerable number of electrolytes have been tried, and great care has been exercised not only in the final result obtained but also in careful measurements of the electrical resistance and the general behavior of the various solutions. To follow the investigators through this research would be outside the precincts of this article; it will be enough to give an account of the laboratory and commercial tests of the two most successful solutions, which, incidentally, threaten to revolutionize protective electro-plating.

The two recommended electrolytes are made as follows:

I B (Serial Number).

$CoSO_4(NH_4)_2SO_4$	200 grams
Water	1000 "

This solution is nearly saturated in cobalt-ammonium sulphate.

XIII B (Serial Number).

$CoSO_4$	312.5 grams
NaCl	19.0 "
Nearly saturated solution of boric acid	1000 cc.

This solution is nearly saturated with cobalt sulphate in the presence of the other components.

In future the solutions will be mentioned by their serial numbers. The laboratory experiments with IB solution showed that cobalt could be deposited from this electrolyte on brass or iron; that the deposits are firm, adherent, hard and uniform, and can readily be buffed to a finely finished surface; that the specific electric conductivity of the solution is much higher than that of corresponding nickel solutions, or, for that matter, of any nickel solution, and consequently will plate far more rapidly than any nickel solution; that no preliminary copper coating is necessary when plating on iron or steel; that the solution does not change appreciably in cobalt content—when a cobalt anode is used, of course—or become either acid or alkaline when used over long periods of time at the recommended current densities; up to 4 amperes per square decimetre, which is equivalent to 37.2 amperes per square foot; that the solution requires little, if any, ageing to put it in condition, but gives satisfactory deposits from almost the start; that the throwing power—that is, power of reaching into indentations in the cathode—is satisfactory; and that the anodes are free from the coatings that are characteristic of nickel anodes. The laboratory experiments with XIII B were even more satisfactory, for, besides possessing all the good qualities of the other, it was found possible to use a current density of from 3.5 to 17.5 amperes per square decimetre; consequently it plates with extraordinary rapidity, and a deposit can be

*Comptes Rendus hebdomadaires des Sciences de l'Academie.

obtained in five minutes that takes an hour with the fastest known nickel bath.

The laboratory results obtained from these two solutions having proved so satisfactory, their formula and the necessary reagents and cobalt anodes were given to the Russel Motor Car Co., of Toronto, with the request that the solutions be given a thorough commercial trial. The company's foreman electro-plater, Walter S. Barrows, after eight weeks' trial during which articles of copper, brass, iron, steel, tin, German silver, lead, and Britannia metal were plated under the same conditions as are met with in nickel-plating practice, found that the practical tests more than bore out the laboratory experiments. Particularly was this the case in regard to speed in plating, for, while in the laboratory the greatest current density successfully employed was 17.5 amperes per square decimetre, equivalent to 160 amperes per square foot, excellent deposits were obtained with 244 amperes per square foot in the practical trials. Articles which usually were given a one hour nickel bath were plated in three minutes in solution XIII B so effectively that the buffer, who did not know of the existence of the cobalt bath, was unable to detect any difference in the finished article. The cobalt deposits not only withstood all the bending, hammering, and burnishing tests usually applied to nickel deposits, but were found to be harder and more ductile than the latter. In fact, so ductile is the cobalt deposit that a 1-inch tube, that had been plated for two hours in the cobalt bath, was drawn down to $\frac{5}{8}$ inch without injuring the deposit. Though cobalt is considerably more expensive than nickel, the increased cost is more than compensated for, when using it for protective plating, by the reduction in cost of labor and decreased vatage capacity necessary for a given amount of work, owing to the greater speed at which cobalt can be deposited from its solutions.

Two other pamphlets published by the Canadian Department of Mines on this subject, are 'Preparation of Metallic Cobalt by Reduction of the Oxide' and 'The Physical Properties of the Metal Cobalt.' In the former, results of experiments are given and advantages discussed of the reduction of cobalt oxide by carbon, carbon mon-oxide, aluminum, and hydrogen. Aluminum is prohibitive, except for laboratory work, on account of cost; hydrogen is to be recommended only when a pure, carbon-free metal is required; carbon and carbon monoxide both reduce the oxide effectively. In the second pamphlet, accounts of experiments of the determination of the density, hardness, melting-point, tensile breaking strength, tensile yielding-point, compressive breaking strength, compressive yielding-point, electrical resistance, magnetic permeability and specific heat of cobalt are given and discussed. Detailed work of previous experimenters also is to be found in this pamphlet. The effect of traces of carbon on masses of cobalt is similar to traces of that element on masses of iron; thus, it was found that while the tensile strength of pure cobalt is about 34,400 lb. per square inch, the addition of 0.06 to 0.3% of carbon nearly doubled it.

The Qualitative Test for Tungsten

By M. L. Hartmann

*The recent activity and interest in tungsten has necessitated research into the methods for detecting this element. It is frequently said that the qualitative tests are uncertain, and it was due to such a remark that this investigation of the sensitiveness of the reduction test for tungsten was begun.

Tungsten minerals, when fused with an excess of sodium carbonate, give soluble sodium tungstate (Na_2WO_4). When solutions of sodium tungstate are made acid with hydrochloric or sulphuric acids, in the cold, a white flocculent precipitate is formed (composition varies from $WO(OH)_4$ to $WO_2(OH)_2$, which on heating becomes yellow tungstic acid or oxide (WO_3 or H_2WO_4). If a strong reducing agent is added, the solution is changed to a bright blue color, due to a suspension of a finely divided, flocculent precipitate, consisting of oxides of composition between WO_3 and WO_2 (sometimes given as $W_2O_5W_3O_8$, W_4O_{11}). If the reduction is carried still further, the brown tungsten dioxide (WO_2) is formed. This change was very slow at room temperatures, the blue precipitate having been kept for two days.

A rather extended investigation was made of the best method for making this qualitative test. For studying the reactions involved, a dilute standard solution of sodium tungstate was prepared. In brief, the following results were obtained:

The reducing agents usually recommended for this test are zinc and hydrochloric acid, tin and hydrochloric acid, and stannous chloride and hydrochloric acid. It was found that the use of tin and hydrochloric acid was the most satisfactory, as the evolution of hydrogen gas was not too violent, and the reduction was very rapid, due to the quadrivalence of tin. The use of zinc and hydrochloric acid was fairly satisfactory, but not as desirable as tin. The evolution of hydrogen was frequently so violent (in the concentrated acid solution required for the best results) that the blue color could not be detected in the solution. Furthermore, with very small quantities of tungsten the reduction was carried to the brown color so rapidly that the blue color escaped notice.

The use of stannous chloride in hydrochloric acid solution is not to be recommended for this test. The blue color was sometimes obtained when the concentration of the tungsten was high, when the amount of stannous chloride was large, and when the solution was heated for some time. Small quantities of tungsten could not be detected, using this reducing agent.

Hydrogen peroxide is sometimes used as a reducing agent in similar reactions. It was found that it did not reduce tungstic oxide either in the cold or when heated.

Oxalic acid is also used occasionally. This reducing agent was without effect on tungstic oxide.

*Abstract from *The Pahasapa Quarterly*, South Dakota School of Mines, Rapid City.

Using zinc as the reducing agent, and hydrochloric acid at room temperature, and sodium tungstate solution equivalent to 0.01 gm. of WO_3, in a total volume of 10 c.c., the blue color became distinct with 0.25 c.c. concentrated hydrochloric acid in one hour; with 0.50 c.c. in two minutes; and with 1.00 c.c., practically instantaneously.

In a total volume of 2 c.c., with 0.5 c.c. of concentrated hydrochloric acid, and with tin or zinc as the reducing agent, 0.0005 gm. of WO_3 could easily be detected by the blue color. Using tin, the color was produced in the cold, while with zinc it was necessary to heat the solution to get an immediate color. If allowed to stand at room temperature, the blue color could be detected in half an hour.

Thus in solutions containing only tungsten salts the test is very sensitive. As small an amount as 1 mg. of WO_3 may easily be detected.

The above experiments were made upon pure sodium tungstate. In order to study the reduction test under actual conditions, ores of known tungstic oxide content were examined. Here, before the reduction test can be applied, the material must be brought into solution as a tungstate or in the form of tungstic oxide in finely divided or colloidal particles. There are two methods which can be used: fusion with sodium carbonate and subsequent solution, or solution of the ore in hydrochloric acid.

The following ores were tested by both methods and the tabulated results obtained:

Material.	WO_3 %	Reduction with tin after Solution in HCl	Fusion, solution in HCl
Wolframite sand	3	No color	Strong blue color
Wolframite ore	16	Strong blue color	Residue blue, but not solution
Wolframite concentrate	32	Strong blue color	Distinct blue color
Scheelite ore	38	Strong blue color	No color
Wolframite concentrate	68	Blue residue, and faint blue solution	Strong blue color
Scheelite	75	Strong blue color	Distinct blue solution, and blue residue

From the tests made on these tungsten materials it was found not safe to depend upon a single method for all cases. Most of the ores dissolve sufficiently in boiling hydrochloric acid to give the blue color on reduction. The low-grade ore did not respond to this treatment. In the method of fusion with sodium carbonate, it was found essential to have a large excess of sodium carbonate. This is to insure the complete transformation to soluble sodium tungstate. It was further found, that for the most accurate tests, the fused mass should be first dissolved in water and then made acid with hydrochloric acid. The reason for this procedure is to insure a colloidal precipitate of the tungstic oxide, which on reduction gives the blue solution, rather than the blue residue which forms when the fusion is dissolved in hydrochloric acid.

In conclusion, the following general directions can be recommended for testing for tungstic oxide in ores. Boil at least 0.2 gm. of finely divided material in a small test tube with concentrated hydrochloric acid until about half of the acid is evaporated. Dilute with an equal volume of water, add a piece of metallic tin (mossy) and heat if necessary. A fine blue color indicates the presence of tungsten. If this test gives negative results, about 0.5 gm. of the material should be fused in at least 4 gm. of sodium carbonate. (This may be done with an ordinary Bunsen burner in a metal crucible, or before the blast in a porcelain crucible). Dissolve the fused mass with boiling water in the crucible. Acidify the aqueous solution with an equal volume of concentrated hydrochloric acid, add a piece of metallic tin, and warm if necessary. The volume of the solution should not be more than 10-22 c.c. A fine blue color indicates the presence of tungsten. In either case, if reduction is continued long enough, a brown color is obtained.

These tests if properly used, will show the presence of tungstic oxide in materials as low as 2%, and by using special precautions, will detect tungsten in even lower-grade materials.

NOTE. The interfering colors that might be produced by other elements present, under the conditions of the test for tungsten, are being studied at the present time. Columbium (niobium) gives a blue color which is said to disappear on dilution and which does not become brown after long reduction. Vanadium also gives a blue color on reduction, but tartaric acid will cause this reduction, whereas it will not reduce tungstic oxide. Molybdenum on reduction goes through a series of color changes from violet to blue to black. Titanium gives a violet color. No other elements are likely to interfere with the test for tungsten.

THE RISE in silver has had the effect of increasing the purchasing power of the Indian and Chinese silver coins. The increase of 30% in the price of silver raised the exchange of China with Europe from 8 taels for a sovereign to less than 6 taels. That is, an Asiatic can purchase with 6 taels an amount of goods that formerly would have required 8 taels. This may have the beneficial effect, it is argued, of increasing the demand for European and American manufactured goods among 800,000,000 Asiatics.

THE PENNSYLVANIA RAILROAD, which operates fast trains between New York, Chicago, and Washington, has not had a single passenger lose his life by train accident during the past two years. In that period 362,000,000 passengers were carried on 2,400,000 trains over 26,000 miles of track, with an equal number of freight-trains running over the same lines. This is a remarkable record.

FELDSPAR production in 1915 was 113,769 tons worth $629,356.

Stoping Hard Ore at Miami, Arizona

By David B. Scott

INTRODUCTION.* When mining was begun by the Miami Copper Co., the hard ground in the western portion of the orebody made it advisable to use a system of wide shrinkage-stopes and pillars. As finally evolved the system was applied to the mining of 2,300,000 tons of ore by the use of stopes and pillars each 50 ft. wide. In this part of the orebody, mining has been in progress since 1910, and the final stages of extraction are now reached. A complete survey of this system can therefore be made, showing the modification of method.

DEVELOPMENT. The preliminary work included the opening of a haulage-level, the construction of a draw-off level, and the driving of sub-levels for stoping. In addition, some extra driving was necessary to determine the boundaries of the orebody, the general outline having been ascertained by churn-drilling. Development was based on stopes 50 ft. wide, with 50-ft. pillars between them. The length of these pillars varied from 200 to 500 ft., at 50 ft. below the floor of the stopes, each drift being beneath the middle of the stopes and pillars. The arrangement made it possible to load along an entire stope without switching or uncoupling. The drawing-chutes were all on one side of the drift, each chute terminating in the draw-off level 25 ft. above. With cars of 3½ tons capacity, the rate of loading was from 3 to 5 tons per minute. In timbering, 10 by 10-in. members were used, sets being spaced at 6-ft. 3-in. centres. The standard set requires a 9-ft. post and 8-ft. cap, the posts being hitched in the ground 7½ in. below the ball of the rail. All drift-set posts are set at a batter of 1½ in. per foot.

A distinctive feature is the draw-off level, 25 ft. above the tram-level. This is used for handling all ore from raises that perforate the stopes, delivering the ore through grizzlies to the tram-chutes. The primary draw-raises branch from each side of the drift and deliver directly into the chutes. The secondary or intermediate raises, used extensively in the pillars, were midway between these chutes, and delivered to them by inclined slides.

CHUTES AND RAISES. The chutes into which the ore was drawn from the stope-raises were all cribbed, 5 ft. square inside, a representative group of chutes showing a life of 12,430 tons each. To eliminate boulders in the tram-chutes, grizzlies were placed over the collars on the draw-level. The grizzly opening was 18 in. square. These grizzlies are several inches above the collar of the raise to permit easy working when ore becomes caught on the grizzly. From the floor of the draw-level, inclined raises on each side of the drift were run up to the edges of the stope, and then funnelled. Vertical raises through the roof of the drift were originally employed, but their effectiveness is doubtful, and they are awkward to use. This arrangement gave sets of two raises in one plane along every 25 ft. of stope. Funnelling of these raises to a top diameter of 20 ft. gave a practically continuous perforation of the stope. The raises were 6 by 6 ft. at the bottom. The back, or hanging wall, constituting part of the roof-pillar between the draw-level and the stope-floor, had a tendency to collapse under weight, but this proved rather an advantage in providing a larger opening for the drawing of ore. Timbering inside of these draw-raises was therefore unnecessary.

Later practice provided raises in the pillars, of the same type as the stope-raises, but the planes of these raises were not in a continuous line with the stope couples, but midway between them. The earlier type of arrangement, with stope and pillar raises all in the same plane, was also tried. This scheme is not as effective in drawing the ore. Intermediate raises also were used in the drawing of 500,000 tons of pillars. These were situated 12½ ft. from the regular raises. To provide an outlet for the ore, these were put up from 'pony-sets' in the roof of the drift, and delivered to slides that ran down into the regular 25-ft. pocket-chutes. These intermediate raises provided double the ordinary number of openings into the floor of the pillar. The requirements of the drawing-level have shown that the drifts can be supported with 10 by 10 timbers spaced at 5-ft. centres, using 8-ft. posts and 7-ft. caps. This type of timbering remains nearly intact after two years of service. On the tram-level a minimum amount of 2-in. lagging should be used, not placed closer than 2 or 3 in. apart. The distance between sub-levels was fixed at 25 ft. Along the axis of the pillars, drifts were run to the limits of the ore. Cross-cuts at 50-ft. intervals were driven each way across the pillars. Raises for handling development-ore were provided at 50-ft. intervals along the drifts. Although in an earlier stage, cross-cuts were driven across the stopes, connecting all of the pillar-lines, these stope cross-cuts came to be regarded as unnecessary. Considerable secondary cross-cutting and raising, however, was necessary during the later pillar mining.

SHRINKAGE-STOPES. The first operation was the funnelling of the draw-raises. This was done at first by cutting out a chamber above the raise and drilling 8 and 10-ft. down-holes with water-Leyner machines around the raise. This proved unsatisfactory because the holes did not break well, and it was difficult to drill deep holes

*Abstract from Trans. Amer. I. M. E. Arizona meeting September 1916.

of nearly vertical pitch with this type of machine. The method preferred was to set up in the raise and drill up holes in a ring. This funnelled the raise successfully to a diameter of 15 to 20 ft. Continuation of this funnelling produced a stope-floor perforated with openings, which practically touched at the rims. Setting up on the broken ore, the ground was squared along the sides of the stope, and any stubs between funnels blasted out. The floor of the stope was thus opened with a back 50 ft. wide and a length of 200 to 500 feet.

Using the entries on the first sub-level, drilling was started along each side of the stope. Steel as long as could be swung in the space was used, and holes from 10 to 15 ft. deep were drilled upward and outward toward the centre. The results were two-fold: at about half of the distance to the next sub-level, entries were broken along the wall of the stope, and a long rib was left in the centre. The principle of caving was adopted therefore in the breaking of this central rib, which was drilled in the succeeding round. After the first cut, the back was maintained on a flat incline until connection was made with the pillar cross-cuts on the level above. Originally use was made of cross-cuts across the stope on the level immediately above, in order to drill down-holes into the back and thus assist the caving of the central portion of the stope. This was not satisfactory, principally because of the difficulty in drilling deep holes, and in getting a wide enough reach across the back. The results did not justify the extra expense of driving these cross-cuts.

After each drill-shift, the excess of broken ore was drawn to allow 6 to 8 ft. of open space between the back and the broken ore. Large blocks of caved ore were bulldozed in the stope when possible, to prevent later plugging of the draw-raises. When connection was made with each successive entering cross-cut on the level above, the back and sides were squared up and the stoping continued upward. The stopes were carried to a maximum height of 125 ft., it being necessary to break to the cap. In a typical stope of hard ore, the expansion in volume due to breaking required the drawing of 39% of the ore in the stope, the latter being full at completion. Drilling was done with Leyner drills, using steel 10—16 ft. long. The maximum footage drilled per shift was 110, and the average footage varied from 60 to 80, according to the number of set-ups required.

Pillar Mining. The process of breaking the pillars was practically the reverse of stoping. Mining was started at the edge of the ore on the top sub-level and carried downward level by level; in each case the 25-ft. roof-pillar was broken through to the broken ore above. This retreating method was desirable for two reasons: it provided a safe exit from working-places; and it insured an even settling of the cap. As soon as the process was started, even in the hardest ground, the speed of working became essential, because the pillar took weight as soon as the cap became dislodged. The mining therefore was done successively on three or four levels at a time at different points of attack, the work on each level being 100 ft. nearer completion than the work on the level below.

Preliminary cross-cutting half way between the original cross-cuts was required to give better drilling faces, especially in the harder pillars. After cross-cutting had been well advanced on the top level, drilling was started at the end of the pillar and across its whole width. Following the first rounds, sufficient ore was removed to give entry to the sloping ore, and drills were set up on the broken ore and long holes drilled in the back. On the top level, as a rule, the ore was not broken nearer than 10 ft. to the cap. Drilling followed strict procedure in retreating from the edges of the pillar toward the central drift, and in the retreat along the central drift as the sides were broken. The roof was carried at a slope of 45°. All holes were drilled in the same direction, pointing away from the line of retreat to eliminate the chance of drilling into missed holes on the next cut. The original raises at 50-ft. intervals were used for removing the excess ore, and generally an intermediate series of raises was put up, making the interval 25 ft. The final development to tonnage ratio for the completed breaking of stopes and pillars was therefore reduced by this work to 45 tons per foot of drift, and 200 tons per foot of raise.

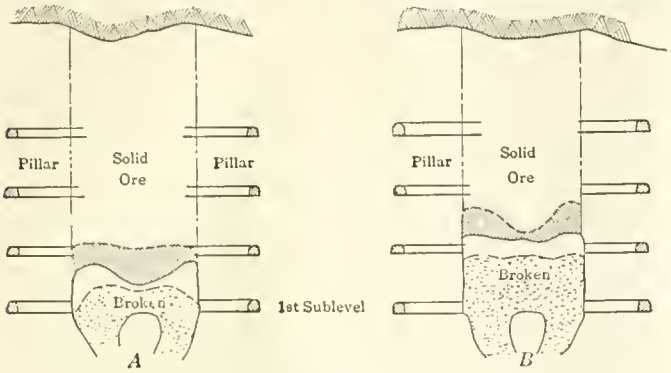
The first round of holes drilled from the level broke to 12 ft. above the sub-level; and the second round, on which long steel could be used, increased this height above the sub-level to 20 ft. It was common to drill through, to the broken ore above, but the remaining arch, 5 ft. or so thick, usually caved when the back was arched for the whole 50 ft. of pillar. At the start the experiment was tried of drilling down-holes in the floor of the sub-level to a depth of 5 ft. to assist this subsequent caving from the level below. It was necessary, however, to case the collars of these holes with 3-in. pipe to prevent fitchering. The breaking of these holes was unsatisfactory, so this practice was discarded.

An important detail of pillar-work was the covering of raises as the work retreated past them. Failure to do this properly would defeat the whole system of breaking, as it allowed the cap to pipe through the raises. Protection against this running of the cap was secured by means of stulls placed in each raise 5 ft. below the level on which breaking was being done, these stulls being hitched in the ground and lagged over. When the same raise was reached on the level below, the process would be repeated and the stull-covering above would then be blasted out, allowing the broken ore to fall to the newer and lower covering.

Mining on the last (or sill) floor of the pillars was subject to modifications by the pony-set raises that split the distance between the regular 25-ft. raises on each side of the pillar. These raises were funnelled in retreat from the end of the pillar, like the regular raises. This funnelling was not carried more than 25 ft. ahead of the pillar-breaking, because it virtually under-cut the entire width of the pillar. Machine set-ups across the raises for the purpose of drilling the back were made on

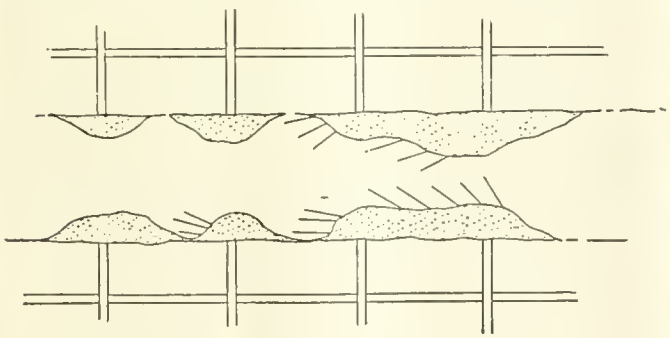
10 by 10-in. stringers that extended across the funnel. This was done to insure against a sudden settling of broken ore in the raise.

Extraction of Broken Ore. Systematic drawing of the broken ore was started when about 70% of all stope and pillar mining had been completed. No draw was permitted within 100 ft. of any mining operations. The drawing of one stope next to a pillar that was in process



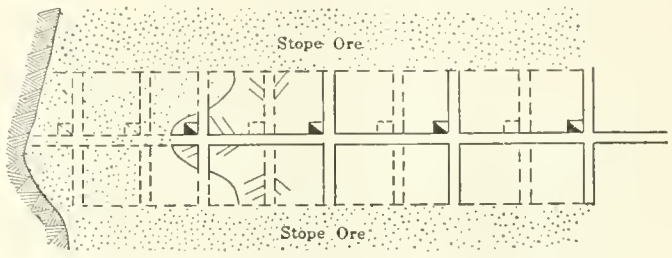
CROSS-SECTION THROUGH STOPE SHOWING POSITION OF ROOF.

of being broken was tried as an experiment, and it caused crushing and swaying of the pillar even in the hardest ground. The question of weight on the draw-off level during the drawing period is an interesting feature. At first there was considerable weight in certain definite portions of the draw-off level, and no weight whatever in other places. This variation in different places was due to a combination of factors: first, the height of cap above the ore in the northern section averaged 340 ft. with a thickness of broken ore of 125 ft. below it. This



PLAN OF STOPE SHOWING DRILLING METHODS.

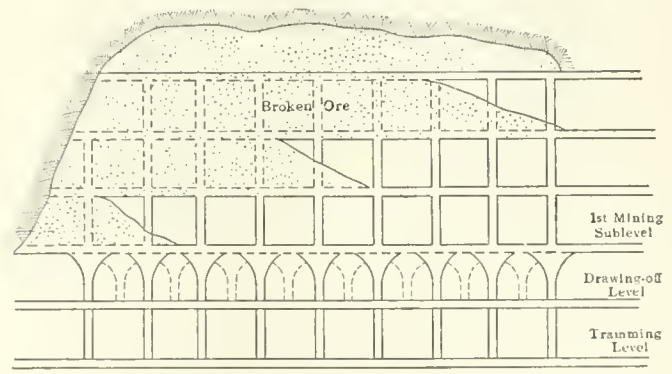
gave a total height of ground of 465 ft. in a moving condition. The southern section had an average cap of 250 ft. and a volume of broken ore over 100 ft. thick, with a total thickness of movable ground of 350 ft. The crushing in the northern section was such as to demand complete re-timbering in some of the stopes. In the southern section, the weight was negligible; only about 20% of the linear footage of draw-drifts became heavy enough to require repair. Second, in a small section where complete breaking of the pillars from top to bottom was impossible, there were some blocks of unbroken pillar above the draw-level. Such parts of draw-off drifts as were below these unbroken areas were always heavy, probably on account of unequal distribution of weight, or the concentration of the weight at a few points. Third, when drawing had become developed on a large scale over a considerable area, the weight did not show any increase, on the contrary, it showed a decided tendency to slacken. Upon the completion of drawing there was little evidence of weight, and the drifts remained open. It is likely that the broken mass of cap and ore reached a state of equilibrium, and that the weight became widely and evenly distributed. In one large section, where all the conditions during mining were satisfactory and the pillar-breaking most complete, about 70% of the timber



PLAN OF PILLAR SHOWING BREAKING DURING RETREAT.

placed three years ago on the draw-off level still stands.

It is apparent that weight was thrown on the draw-drifts and not on the pillars between these drifts, as shown by the presence of untimbered cross-cuts through these pillars. That the draw-off level took all the weight so that the tram-level was left intact, is shown by the present condition of the latter. Sections of the tram-level beneath badly crushed draw-level drifts do not even require lagging in the roof, and 8 by 8-in. drift-set



LONGITUDINAL SECTION THROUGH PILLAR.

timbers that have been in place nearly five years show no weight. This is one of the pronounced advantages of the draw-off level. The repair on the draw-off level did not cost over 10c. per ton of ore drawn on any stope or pillar line, and went considerably below this cost on the tonnage served by the entire draw-off level. Repairing was facilitated by chutes every 25 ft. along the drifts.

Control of the draw was essential for an even lowering of the cap, and to permit a retreat from the western to the eastern limits of the section. This required the pulling-down of the cap on an incline of 15° toward the western, or completed, portion. The drawing of a series of chutes in a plane at right angle to the direction of retreat, or across the stopes and pillars instead of along one

whole stope, was the most satisfactory method of getting the ore to run readily. When the draw was started there was difficulty in regulating it. The nature of the ore and the length of time between stoping and drawing, caused the chutes in some areas to pack tightly. An idea of the compact nature of broken ore under pressure can be gained from the fact that occasional cross-cuts were driven from pillars into shrinkage-stope ore, and that no timbering was required for some of these drifts in broken ore. Starting of the chutes in these stopes required special methods. One of the most satisfactory was the use of small pony-set raises in the back of the draw-off drift midway between the raises. This involved running an inclined raise for 15 ft. each side of the drift to the broken ore. When a hole was drilled into broken ground, the raise was funnelled immediately, and blasting of this round loosened the ore, usually including that in the adjacent raises. A series of these pony-set raises sufficed to make the ore run readily in the regular raises. This method had the disadvantage that the pony-sets took weight and were expensive. The second method, which involved no extra raises and was otherwise satisfactory, employed a system of breaking the arch of hung-up ore. Entry to the back of packed ore was made through the raises, and large stulls were placed against the hung-up ore. Small drifts were then started in the foot-wall of the raise and run parallel with the long axis of the stope, at about 15 ft. above the draw-level. Those drifts were driven in solid pillar ground and connected a series of hung-up raises. Starting at the end of the drift the ground was drilled vertically and horizontally across the stope. When these holes were blasted the legs between the regular raises were knocked out and an arch of broken ore left. Arches 40 ft. across and 30 to 50 ft. thick were not uncommon in this work, but these arches invariably collapsed, bringing down the stope ore. In this work the hung-up ore would not cave, even if the next raise 25 ft. away was running regularly, so that there was little danger underneath the broken ore, and no accidents occurred. Choking of chutes was caused occasionally by packing of ore in the bottom of the inclines. It was also necessary to blast out part of the brow of the raise over the chute to prevent plugging with boulders. It was desirable to eliminate blasting in chutes and a separate squad was detailed for this.

Over a period of a year, with a production of 400,000 tons, the average rate of drawing per shift was 118 tons per man. The monthly range was from 94 to 142 tons per man. Under favorable conditions the tonnage per man has exceeded 200 for several shifts. The largest individual output reached on one shift was 400 tons by one chute-man. The cost of drawing this ore into the tramming-chutes amounted to 3.7c. per ton over a year for direct expense of labor and explosives. Where special methods were required in the case of hung-up ore, the cost for short periods went as high as 15c. per ton. The result of drawing 1,700,000 tons in one section of the work showed an estimated recovery of 95% of the original tonnage. Individual records were kept on each stope and pillar, and although the drawing from these is undoubtedly interchanged, the figures favored the stopes over the pillars by about 10%. The harder ore showed greater ease in drawing and better extraction than the softer areas, because the latter packed under pressure. The compression of broken ore is an important factor, as it increases the tendency of the chutes to ravel vertically toward the cap without drawing laterally. Even under moderate pressure, the broken ore tended to stand nearly vertically around the rim of a chute. The angle of repose was found to be 80 or 90°. In a small number of chutes where the ore was greatly packed, the ore drawn corresponded in volume to a cylinder with a diameter of 14 ft., and a height up to the cap. A large number of draw-raises per unit of area, rather than a large area in the funnelled mouth of the raise itself, is desirable for best extraction.

Secondary Recovery of Ore. It became obvious that some clean broken ore remained in the stopes and pillars. This remainder probably stood in the shape of a wedge directly over the draw-drifts, and also along the boundaries of the old stopes and pillars. To recover the ore above the draw-drifts, the backs of the latter were shot-down to the floor of the stope. This work was done in retreat, and the ore drawn on the incline into the tram-chutes at a cost of 15 to 25c. per ton, the output per man averaging 40 tons. Results obtained from these operations confirmed the view that the clean ore stood in a series of wedges or cones with an apparent base of 20 ft. and a height of 50 ft. To recover the ore standing where the old pillars joined, a series of drifts midway between the original drawing-lines was driven. These drifts were at the same elevation as the draw-off level. Dump-chutes and supply-raises were provided from cross-cuts on the tram-level at 200-ft. intervals. The drifts were supported by 12 by 12-in. timbers set 4 ft. 2 in. centre to centre, and chutes were placed in each set staggered along the drift. The back was broken on top of the lagging, and a small shrinkage-stope about 20 ft. wide excavated until loose ground was encountered, or until caving occurred. The ore drawn from the chutes was trammed in 1½-ton cars to the main tram-raises, the maximum tramming being 100 ft. This marked the last stage of the process of mining.

Production of crude barytes in the United States in 1915 was 108,547 short tons, valued at $381,032. As compared with the production in 1914, which was 52,747 tons, worth $155,647, this is a remarkable showing. Reports collected by James M. Hill, of the Geological Survey, indicate that the production in 1915 will be continued, if not exceeded in 1916. Missouri contributed 39,113 tons, Georgia 31,027 tons, and Tennessee 25,074 tons. Alaska shipped its first barytes in 1915. The general feeling of the trade is that this boom is not to be short-lived, particularly in view of the large demand for crude barytes by the newly-established barium chemical industry.

Mining in Arizona

By Charles F. Willis

The rise in the price of silver has given a finishing touch to the metal market. It means much to this State and has already stimulated transfers of property. A local newspaper without the record of several mining deals is becoming rare. These are not all small deals, involving the sale of a few claims for a few thousand dollars, but deals involving the transfer of large properties, upon which many thousands of dollars will be spent, and ensuring the re-opening of old producers.

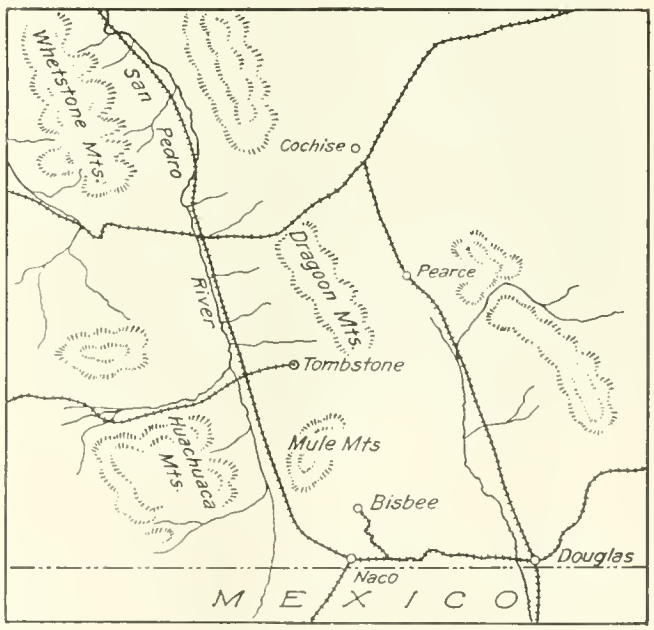
A deal has been consummated in Cochise county for $600,000. The claims, 14 in number, are those of the Leadville Mining Co., of Courtland, a local organization. The president of the company is William Holmes, and the secretary, William Monmonier of Pearce. The company has been at work for a number of years and the property has been under option a number of times to different parties. The stockholders have received part-payments on their holdings once or twice on account of these pending deals. The present option taken by the Needles Mining & Smelting Co. provides for the payment of $600,000 before one year, the sum of $10,000 to be paid as soon as the optional agreement is ratified by the stockholders at their meeting to be held at Pearce on June 3. The company is to allow the present lessees, now at work on the property, to continue under the same conditions, the royalty to be paid into the First National Bank of Los Angeles and held on deposit as part of the purchase price in the event that the property is taken over. The option requires that at least 10 men shall be employed continuously, that assessment work on the unpatented claims shall be done, and the Maid of Sunshine shaft sunk at least 80 ft. deeper and certain drifts run in that claim.

The Needles company is a subsidiary of the United States Smelting, Refining & Mining Co. A. P. Anderson, the general manager, is said to be a man of wide experience.

Another important deal in which a quick turn was made, is that of the Sitrue mines, in the Huachuca range, better known as the Exposed Reed property. This group of claims had been taken under option in April by Owen T. Smith and J. P. Steel, from Albert Steinfeld of Tucson for the sum of $40,000. Messrs. Smith and Steel then left for New York, where they succeeded in placing the property with Charles Starek for the sum of $250,000. The option required the payment of $25,000 before June 10 of this year, and for the payment of $25,000 every ninety days after, until $225,000 has been paid. Work must be started in 30 days, and active development work continued. The property is to be worked for tungsten instead of gold. There is some machinery on the mine, and a mill and concentrator will be installed. The ore is scheelite in wide quartz veins.

George A. Brown and his wife of Dragoon have sold 80 acres of their homestead for $30,000 to S. H. Worrell of El Paso. The land lies in the wolframite district between Dragoon and Johnson. The terms call for the payment of $3000 on the signing of the papers, for the payment of $13,500 within six months, and the remainder at the end of a year. The land is now being worked for wolframite both by placers and shafts. Mr. Worrell intends to install a concentrator.

Henrietta Franklin and husband have sold to Thomas R. Sorin the Bonanza claim in the Tombstone district. The property at one time produced high-grade silver ore. Charles Morgan has sold to J. L. McWilliams of El Paso an undivided one-sixth interest in three claims in the Hartford district. H. W. Rector has sold to R. T. Burlingame the Rector claim in the Warren district. George W. Cox has sold to William H. Johnson the Lid claim in the Cochise district.



The San Juan mine, on the Graham county side of the mountains of the Clifton-Morenci district, has passed from the ownership of local people to F. W. Estabrook. Details were not given out. Mr. Estabrook is a member of the board of directors of the Miami Copper Co. His representative was Ethridge Walker, mining engineer, who will be the president of the new company. The 12 claims of the San Juan company were originally located by a woman who came out from the East and prospected in the Lone Star district. Subsequently she was able to interest capital and a development company was formed, which resulted in some development of the claims, the deepest work being done at 335 ft. The records show that over $300,000 worth of ore was shipped when, owing

to a disagreement between the stockholders and the management, and the further fact that copper had dropped to 9 cents, the company ceased operations. The Arizona stockholders did the required assessment work and it was from them that the property was secured last February by R. W. Craig, Gus Hirschfield, T. J. Sparks, and J. C. Adams. The transaction was promoted by Louis A. Dunham, who figured prominently in the sale of the Inspiration and Ray copper mines. During the short time the above-mentioned owners had the property, nine cars of ore were shipped to the C. & A. smelter at Douglas, the returns showing an average value of $14.34 per car. In addition, a number of churn-drills have been operated, the last report of the company indicating 970,000 tons of ore averaging 3.67% copper. The recent work at the mine has been in charge of Sam Fields who was previously a superintendent at the Calumet & Arizona mine and later at the Ray Consolidated. After he had worked on the property 90 days, Mr. Fields became a shareholder in the company. The rumor that the Lewisohns are associated with Mr. Estabrook in this venture has been denied, but with the statement that other Miami company stockholders are concerned in the purchase.

The Old York group of gold mines, situated a mile south of Yarnell, is now active under an option given to Bliss, Wilson & Co. of San Francisco. A modern equipment has been selected, including an air-compressor and hoist. The machinery is on the way from San Francisco. The Old York has been explored extensively, the main shaft reaching to 400 ft., with several thousand feet of workings. It will not be a public-stock company; D. C. Burtt of San Francisco is to be superintendent.

Details regarding the re-organization of the Inspiration Needles Copper Co. and the acquisition of 11 claims adjoining the property in Live Oak canyon, just west of Miami, have just been disclosed. The company secures control of 525 acres of mineralized ground much the same in surface characteristics as the Live Oak group of the Inspiration Consolidated Copper Co. Within 10 days three churn-drills, leased from the Inspiration Consolidated, will be operating. Nothing more than location work has been done, although the belt on which the great low-grade orebodies of the Inspiration Consolidated are found extends through the ground. A number of engineers have made favorable reports on the property, but complications have prevented development. With the claims in one group, their value is much greater than when they were held by several owners. Harry Lefkovits, a merchant of Phoenix and Miami, promoted the reorganization of the company. Dan R. Williamson, for many years the principal stockholder of the company, continues president and F. W. Hamm is secretary. The company is capitalized for $2,000,000 in $1 shares. Original stockholders and claim-owners have received 1,200,000 shares, and the remaining 800,000 are in the treasury. A block is to be sold at 50c. per share to raise a fund for development. The first issue of the stock was subscribed within a few hours at Miami and on the Boston and New York curbs.

The Bisbee-Ajo Copper Development Co. is the latest organization to bid for favor in the Warren district. This property is in the Sonoita range of mountains, 22 miles south of Cornelia; it includes 21 unpatented claims, known as the September Morn group. The ground was located in September, two years ago. The claims include a hill of schist and monzonite, impregnated with copper sulphides; chalcocite, bornite, and chalcopyrite. In places high-grade ore outcrops, and there is every indication of large bodies of concentrating material. The company is capitalized at $650,000, the shares having a par value of $1 each. Of this stock, 150,000 has been pooled for the promoters, and 100,000 shares, it is understood, have been put on the market at 25c. per share.

A mining deal that may lead to developments in the Globe-Miami district, which has long been neglected, was closed when William Buckland transferred to T. J. Minck, of New York, 16 gold claims on the eastern slope of the Pinal mountains, eight miles south of Globe. Buckland has spent many years prospecting that part of the district, and his efforts were rewarded by the discovery of gold in paying quantity, some of the ore assaying as high as $50 and $60 per ton. Working alone, and with scarcely enough money at times to buy powder and fuse, Buckland has sunk a number of pits and shallow shafts, and has found the best ore in the deeper openings. The road from Globe to Winkelman by way of El Capitan will run within a mile and a half of these claims.

Gold in Russia

The French paper *L'Information* gives the following details with regard to gold in Russia: "The Russian Government, anxious to increase the gold reserve of the State Bank, and to favor the production of gold within the Empire, has decided to accord for gold brought voluntarily to the laboratories or to the bank a premium of 45% on the pre-War price. Unfortunately, notwithstanding the prohibition of gold exports, the receipts of gold have barely increased; for merchants purchase the metal and send it abroad by the Asiatic route. In these circumstances the Russian Minister of Commerce and Industries has decided to ask for power to requisition gold in the hands of private people, payment to be made therefor, plus the premium of 45% as stated above."

KENNECOTT COPPER CO. produced 57,500,000 lb. of copper in its seven months of operation during 1915 at a cost of 4.54c. per lb., of which nearly one-half was the freight from the mines in the interior of Alaska to the Tacoma and Garfield smelters. An ammonia-leaching plant, somewhat similar to that of the Calumet & Hecla, is to be built for treating tailing from the mill. The grade of the ore mined last year averaged 60% copper. The production for 1916 is estimated at 120,000,000 lb.

A Portable Equipment for Prospects

By Louis A. Rehfuss

The tendency of the age is the worship of Bigness. Nothing so catches the eye of the public as the announcement of some monster material achievement, whether it be the building of a Panama Canal or the construction of a new sky-scraper. So we need feel no surprise that our technical mining literature today should reflect the same craze and be filled to over-flowing with articles describing giant machinery or new processes to extract the last drop of blood out of a stone. This tendency would be perfectly commendable were it not for the fact that in their rush for efficiency and bigness our engineers have neglected to discuss the problems presented by the prospect and small mine, so that it is but seldom that the small operator can find anything of immediate value in technical journals, despite the fact that there are ten small mines and prospects operating for every mine of size sufficient to render the more ambitious articles necessary. There is more especially a demand for information as to what machinery is available on the market in complete units and yet small enough for prospects.

To discuss this question is the object of this article and more particularly to describe the plant we are using today in developing a prospect here at West Point, California. Suffice it to say that this outfit, which includes power, compressor, drills, air-hoist, and pump will not in the aggregate weigh over three tons, with the heaviest unit only 1800 pounds, so that the whole outfit may be moved at small expense from prospect to prospect until a mine is developed. Having been in use by us for two and a half years with complete satisfaction, it is no longer an experiment.

Operating in the East belt in the granodiorite formation that surrounds West Point, we soon realized that if we were to make much progress we must have a machine-drill. At the same time the undeveloped condition of the prospect did not warrant heavy investment in the shape of mining machinery. Most of the mines in this region use the abundant wood supply of this timbered country to fire steam-boilers, but their boilers are heavy and cumbersome, and rather wasteful of wood, so that wood-choppers' wages are a considerable item each month. Therefore we purchased a 16-hp. Clay marine gasoline engine. This engine is an upright two-cylinder machine weighing 1800 lb. An investigation of horizontal stationary engines of the same power showed that they are relatively clumsy and far heavier, and consequently unfitted for our purpose. The marine engine has given excellent satisfaction and we found it required but light foundations. A couple of logs laid lengthwise and parallel with cross-pieces for the engine and compressor, mounted at the opposite ends, has served us excellently with scarcely perceptible vibration.

For the compressor, a Rix duplex-vertical machine, 6 by 6, serves admirably. It has a capacity of from 45 to 80 cubic feet of free air per minute up to 100 lb. pressure, or sufficient for one hammer-drill. This compressor weighs only 1000 lb., but is designed to run at rather high speed from 225 to 400 r.p.m. Owing to an efficient system of lubrication, however, it stands up well under service, and, in fact, after two and a half years of work, we can testify that this machine has done remarkably well—the only cost for repairs in that time amounting to three or four dollars. We have not had occasion to tighten a single bearing in that time. The compressor was, of course, belted to the engine, and the speed of the engine mentioned with the fly-wheels provided we found to be suitable without reduction or alteration in any way.

THE LEADVILLE DRILL-COLUMN HOIST IN USE.

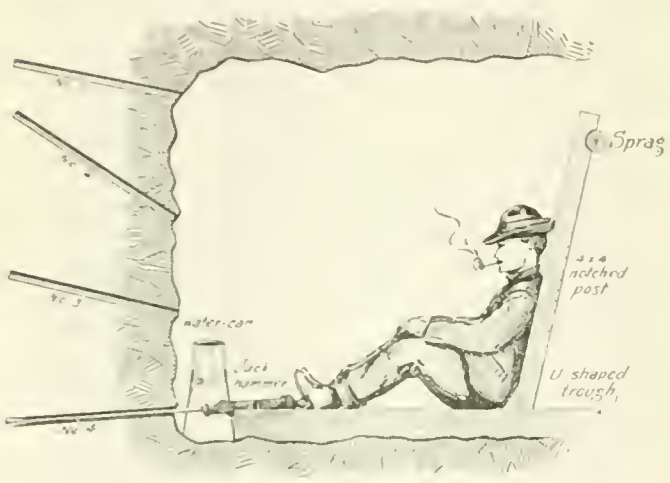
There are now on the market direct gas-driven compressors that form compact units. They are, however, somewhat heavier than the combined units mentioned and are rather more expensive. These direct gas-driven compressors are made as small as 66 cu. ft. in capacity.

All of our drilling we do with an Ingersoll-Rand butterfly stoper and an Ingersoll jack-hammer, using these for overhand stoping and sinking respectively. In driving we employ the stoper to drill the upper rows of holes, while the lifters are drilled with the jack-hammer in the method shown in the sketch, sliding the drill down a U-shaped wooden trough by foot pressure. This is a peculiarly easy method of utilizing the jack-hammer for such work. The notched post from which the uppers are drilled with the stoper forms a convenient back-rest in

drilling these lifters. The cut, of course, is made by rows No. 1 and 2. We have tried many types of rounds, but we find a round drilled as shown about the most satisfactory it is possible to get in using a stoper and jack hammer for driving. Unless the ground is quite tight, it will break practically to the bottom of the holes.

During the last few years excellent hammer drills have come on the market that can be used for all three functions, driving, stoping, and sinking. These are provided with a light column. Among such types may be mentioned the Waugh stoper, the Ingersoll 'Mounted Jackhammer,' the Sullivan pneumatic-feed, and others. One of these would probably make the best unit for a prospecting equipment limited to one drill. The heavier types of drills are precluded because of their large air consumption.

For hoisting we employ a Leadville drill-column hoist. This is a veritable pocket hoist, but when one has air



A COMFORTABLE METHOD OF DRILLING.

available for drilling, it certainly beats windlassing all hollow. By using two buckets, one being hoisted while the other is lowered at a depth of 100 feet, it will give the trammer all the work he wants to do. It will hoist loads up to 500 lb. There are several varieties on the market, including the Ingersoll-Rand 'Little Tugger' and the Holman 'Stretcher Bar' hoist, besides the Leadville type mentioned. They all operate on compressed air, and while designed to operate on a column, can be readily installed as a surface equipment. The total weight of the Leadville hoist without the column is only 250 pounds.

A small steam-pressure pump, of capacity 30 gal. per minute, will run quite well on the compressed air available and will be found large enough for most prospects in the early stages at least. Outside of a tendency to freeze now and then, this equipment gives pretty good service.

With the small amount of air available, it is not possible to perform the three operations of drilling, hoisting, and pumping at the same time. They must be performed separately. A little adjustment of routine, however, makes this work out satisfactorily. The fuel-cost is quite low. Since freight on fuel was the same in all cases, and gasoline gave better results than distillate, we used gasoline. Where the equipment is employed pretty steadily throughout the shift—drilling, hoisting, and pumping—it will be found that the gasoline used will seldom average over $1 per shift. So far as attention goes, it is practically nil. The engine may be started up and left to itself. It needs no attendant, no costly fireman to sit around and eat the profit. The factor of idle hands is one of the most potent of all in killing many a good prospect. A mine that is operating one machine-drill cannot afford to have a blacksmith and helper, as we have seen at some mines. Two or three hours work per day on the part of two men will attend to all the necessities of blacksmithing and do in our case, after which these men can start drilling or anything that may come along. By employing four men, two on each of two shifts and having them perform whatever comes along, it will be found that the above outfit will permit of a considerable amount of work being accomplished at a very moderate cost.

MANY MINING COMPANIES are providing buildings where the miners may remove soiled working-clothes, bathe, and put on clean, dry clothing before returning to their homes. Most workmen nowadays like to go to and from their work dry and clean. In many instances miners' cottages have no running water inside and it is a burdensome task to bathe at home. In addition to its cleansing effect, the shower-bath refreshes the tired workman so that he goes home in a more agreeable frame of mind. It is interesting to note that some of the best change-houses are to be found in Michigan, Minnesota, and Alabama, although those States have no law requiring such houses. Some of the earlier change-houses were not kept clean, and so fell into disfavor, their equipment breeding vermin. In some of the earlier buildings a wooden locker was furnished each man. This one locker was used both for street clothes and mine clothes. Because there was no circulation of air in the lockers, the mine clothes would not dry and the miner was forced to put on damp clothes for his day's work. The perforated metal locker has supplanted the wooden locker; and in order to keep the mine clothes separate from the street clothes, two lockers have been furnished each man. The one for street clothes is made of expanded metal, well perforated. The mine-clothes locker is of sheet metal and is as air-tight as possible, except for the vent-pipe at the top. Other lockers have upper and lower compartments, the upper for mine clothes and the lower for street clothes. A steam-pipe is run through the bottom of the upper compartment to furnish heat for drying the mine clothes.—U. S. Bureau of Mines. TECHNICAL PAPER No. 16.

SPOKANE, Washington, a city of 140,000, is a convenient centre for Coeur d'Alene mining. It is an enterprising attractive city with broad streets and modern buildings. The people of the surrounding region, which includes parts of several states and of British Columbia, like to speak of Spokane as the centre of 'The Inland Empire.'

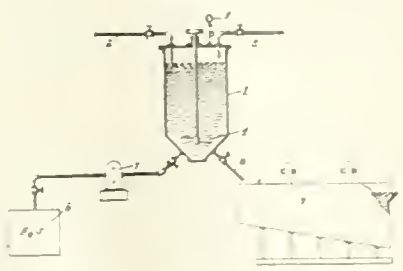
1. A thickener comprising a tank, a curved blade therein arranged adjacent the bottom thereof and having a plurality of convolutions in a plane intersecting its axis of rotation at an angle, the successive convolutions of the blade lying closer together as the blade progresses inwardly, and means for rotating said blade about said axis.

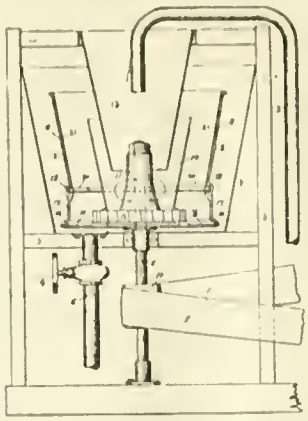
1,180,816. Flotation of Minerals. Raymond F. Bacon, Pittsburg, Pa., assignor, by mesne assignments, to Metals Recovery Company, a Corporation of Maine. Filed Aug. 14, 1914.



1. The method of effecting the separation of oxidized ores from associated gangue, which consists in subjecting the mixture, in a finely divided condition, to the action of hydrogen sulfid under pressure, and finally subjecting the mixture to flotation: substantially as described.

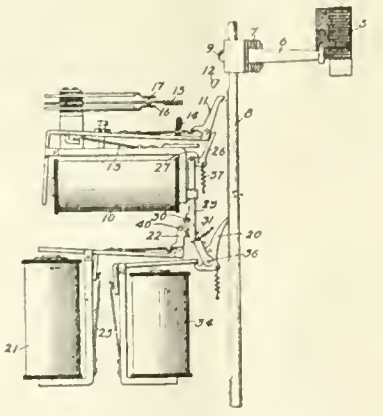
2. The method of effecting the separation of oxidized ores from associated gangue, which consists in subjecting the mixture, in a finely divided condition, to the action of hydrogen sulfid under a pressure as high as 20 pounds to the square inch, and finally subjecting the mixture to flotation; substantially as described.

1,181,695. Gold-Separator. Jerome W. Sweet, Half Moon Bay, Cal. Filed Nov. 17, 1913.



1. In a centrifugal apparatus for separating the valuable from the worthless parts of fine ore, the combination of a revolving bowl, a series of vanes extending outwardly from the centre of the bowl, a chute delivering material to be treated into the bowl directly above the vanes and near their inner ends, a depression for the heavier and larger particles of value located between the outer ends of the vanes and the wall of the bowl and communicating with a collecting groove formed in the wall of the bowl in the plane of the said depression, and means for collecting the lighter particles of value carried by the wall of the bowl and located above the said depression and the groove.

1,180,814. Process of Extracting Copper From Its Ores. William E. Greenawalt, Denver, Colo. Filed Sept. 30, 1912.



1. A process of extracting copper from its ores which consists in treating the ore with a chlorid solution to dissolve the copper; separating the solution from the gangue; treating the copper solution with sulfur dioxid to convert the cupric chlorid to the cuprous chlorid and regenerate acid; then treating the solution with hydrogen sulfid to precipitate the copper as sulfid and regenerate more acid; separating the regenerated acid solution from the sulfid precipitate, and returning it to the ore.

1,178,191. Copper Precipitant. Henry Livingstone Sulman and Hugh Fitzalis Kirkpatrick Picard, London, England, assignors to Minerals Separation American Syndicate (1913) Limited, London, England. Original application filed Dec. 27, 1913. Serial No. 808,986. Divided and this application filed June 15, 1914. Serial No. 845,086. (Cl. 23—13.)

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

GOLD OUTPUT.—DRAINAGE-TUNNEL.—MILLS AND LEASES.

Gold production of the district in June, as reported by the mills and smelters, is as follows:

	Tons	Grade	
Golden Cycle	36,000	$17.00	$612,000
Portland	12,000	21.00	252,000
Portland	17,800	2.78	49,484
Portland	11,890	2.12	25,207
Smelters, Denver and Pueblo	4,360	55.00	239,800
Caley-Jerry Johnson	1,800	3.50	6,300
Worcester-Rubie	300	3.50	1,050
Total	84,150	$14.09	$1,185,841

For some months the plant of the Golden Cycle company at Colorado City has been undergoing extensive changes and additions. The capacity of the mill at present is 1500 tons daily, instead of 1000 tons as before.

During May the advance of the Roosevelt drainage-tunnel was only 150 ft. The work of carrying forward the heading was considerably hindered by the necessity for enlarging the station at the point of connection with the Elkton shaft, and the sinking of a sump below the tunnel-level at that point.

Work on the foundations for the new Portland sampler is being rushed forward. Excavations for the concrete piers are about completed. Timbers for the frame-work are put together and are ready for erection. Steel I-beams and other structural members are arriving daily.

It is reported that the group of claims comprising the Rose Nicol property, situated on Battle mountain and Bull hill, has been leased to Edwin Gaylord and associates for five years.

J. F. Burns of Colorado Springs heads a new company to be known as the New Era Leasing Co. This corporation has been formed to develop the Minnehaha claim of the Jennie Sample Consolidated Mining Co. E. P. Arthur, Jr., of Cripple Creek, is reported to have charge of operations for the new company.

Rumors have been circulated during the past week that another 'Cresson vug' has been uncovered by lessees on the Queen Bess lode on Tenderfoot hill. While not as extensive as the famous 'jewelry shop' of Raven hill, the ore is being sacked and should give handsome returns to the fortunate lessees.

OURAY, COLORADO

FLOTATION AT THE ATLAS MILL.

The increase in the price of silver is stimulating mining in this district, and there are a dozen or more properties being worked within a radius of 10 miles of the town. Probably the largest producer in the district at present is the Atlas Mining & Milling Co., operating its mine and concentrating plant near Sneffels, which is 10 miles by wagon-road southerly from Ouray. The ground is covered by snow most of the year, the altitude being 12,000 ft., with the mill 800 ft. lower.

The company has recently installed at the mine a Westinghouse storage-battery motor capable of hauling 21 empty and 10 loaded 1-ton cars. Ore is carried from the mine to the ore-bins, from there by aerial tram to the mill, 1800 ft. distant. This locomotive has proved economical and entirely satisfactory.

A brief description of the mill, shown in the accompanying photo, is as follows: Though lacking in any unique features, it is somewhat famous as being the first plant in the United States to successfully concentrate silver-lead ore by flotation. The ore first passes through gyratory-crushers, then to 20

ATLAS MILL NEAR SNEFFELS, COLORADO.

stamps. The product from these flows to two Wilfley tables, then elevated and classified. The plug product from the classifier goes to Hardinge mills, and the overflow direct to flotation machines. Wilfley tables get the oversize, and the slime is fed to flotation machines.

In the flotation department an 8-compartment Minerals Separation and a 3-compartment Hebbard machine are operated. The first cell of the M. S. machine is used as a mixer, the second and third, and sometimes the fourth, cells are skimmed for concentrate, the remaining cells for middling, while the Hebbard machine is skimmed for middling only, which is re-

turned to the first cell of the M. S. machine. Concentrate is sent to the dewatering tank, and overflow returned for retreatment. From the dewatering tank the concentrate is hauled by hand-cars to the inclined drier. This is a wooden trough, 20 in. wide by 18 in. deep, and approximately 90 ft. long, having three steam pipes fitted longitudinally on the bottom, over which the concentrate is allowed to flow by gravity, accelerated from time to time by four or five men stationed at various points along the incline, which leads directly to the sacking-house, where the concentrate is sacked and shipped by wagon to Ouray, and trans-shipped by train to the smelter at Salida.

The flotation medium here is a mixture of fuel-oil and pine-oil, although creosote and other oils work apparently as satisfactorily. The recovery recently made is 91%, which must be extremely gratifying to the management of the Atlas company, of which James A. Lannon is superintendent with A. B. Shipman in general charge.

SILVERTON, COLORADO

Ore Treatment at Silverton and Gladstone.

The Mears-Wilfley company is re-modeling its concentrating plant near Silverton, installing an additional Minerals Separation flotation machine of five compartments, also another tube-mill, 5 ft. diam. and 16 ft. long, manufactured by the Denver Engineering Works. With this extra equipment the mill will have a capacity of 500 tons per day. The company intends to treat tailing from the old Silver Lake mill, as has been done in the past, raising it by a specially designed pump, (centrifugal type) from the lake to the creek-bed, which carries the pulp a mile or so, then by flume two miles long to the concentrating plant. Here the tailing is re-ground to 40-mesh, and concentrated by Wilfley tables and flotation machines. The mill is expected to be in operation by the middle of July.

The Kittimac Mines Co. of Wyoming, with head office at Denver, is operating its mill 4¾ miles north-east of Silverton, using the usual crushers, tube-mills, and concentrating tables. A lead concentrate is obtained direct from the tables. The zinc heads are sent to a drier, later to be treated by three Huff electro-static separating machines, making a product containing 48 to 52% zinc. The iron concentrate carries 10 to 16% copper and $20 per ton gold. The company has ordered and will install at once a flotation machine to treat the tailing, built by the Dale & Tanstead company of Silverton. The mill has a capacity of 135 tons per day, the ore being carried from the mine by aerial tram, two miles in length. D. B. Carey is president of the company and A. Malchus is manager.

The Gold King Leasing Co.'s mill at Gladstone, which has been closed since February, is now operating with a full crew. The capacity of the plant is 250 tons per day. The flotation machine of 40 cells is giving great satisfaction. L. O. Bastian is superintendent and J. H. Slattery general manager. The head office of the company is at Silverton.

ELY, NEVADA

Notes on a Probable Copper Producer.

Announcement that at a meeting held a few days ago at New York officials of the Consolidated Coppermines Co. had subscribed $100,000 with which to rehabilitate this property is considered most important for this part of Nevada. This company controls the most extensive area of any in the district, which almost surrounds the Nevada Consolidated. Engineers predict that it will eventually prove to be a prolific copper producer. It is understood that the old Giroux mill will be re-modeled and a flotation plant added for treating 500 tons per day. Negotiations are said to be progressing favorably for the Nevada Con. to treat a minimum of 1000 tons per day. Revival of this property will add several hundred men to the pay roll of the district, and greatly increase the output.

The history of the Coppermines before and since the consolidation of the various interests now included in the holdings has been a long run of misfortune, internal dissensions, and litigation, the end of which now seems to have been reached through conciliation of all factions. Identified with its management, control, and as large factors have been such noted operators as Giroux, Cole, Ryan, Wall, and others who have seldom been in complete harmony regarding the operations of the property. Managerial operating, and financial troubles have nullified almost every effort to place the property in its right position among the great copper producers of the country.

After the loss of the Giroux shaft, by caving, to a depth of about 1300 ft. a few years ago, the Cole management sank a new shaft of five compartments, equipped with a splendid hoisting-plant; but at a depth of about 1000 ft. they encountered an immense flow of water, which was followed by a fire that wrecked the shaft. In the meantime, churn-drilling has been conducted over a large area, with excellent results reported, and a considerable production has also been made from a part of the property by means of work of the Nevada Con., which has extended its workings into this ground for acquiring convenient access to one of the steam-shovel pits. In former work at the Giroux, large bodies of high-grade oxide ore containing 25% were developed, and other work has proved the existence of immense deposits of sulphide ore over a large area.

GUADALAJARA, MEXICO

Composition of Zapatista Silver Coins and Money Problems.

Having an opportunity recently to assay and weigh some Zapatista silver pieces I include the results as under. These are of interest because of the varying fineness in gold and silver, the decrease in the weight of the pieces the second year and also, not unexpected, the pieces being marked with a gold content which they do not contain. The pieces assayed were P1 and P2 for 1914 and 1915 respectively. The workmanship is poor. There is much speculation as to the value of these pieces, and many have the idea that they are worth several times their stipulated value on account of the gold they contain. It is probable that pieces of the same denomination and with identical markings vary greatly in silver and gold content.

Piece peso	Year	Weight grams	Marked gold grams	Fineness Ag	Fineness Au	Actual gold grams
1	1914	14.8	0.3	862	29.0	0.43
2	1914	25.1	0.595	856	13.8	0.327
1	1915	12.2	0.3	892	3.2	0.039
2	1915	18.7	no mark	785	9.8	0.183

The money question in this part of the republic is becoming exceedingly complex. A short time ago local editions were declared out of circulation, and on June 3 the twenties, fifties, and hundreds of the editions Vera Cruz-Gobierno Provisional and of the Ejercito Constitucionalista, were declared out of circulation, all without previous notification. For a few hours in the morning of June 3 business was done with this money, and at about ten o'clock in the morning it was declared officially out of circulation. Of course the Government promises to redeem this money during July, and pay double its present value in gold to those who show their confidence by depositing their money for redemption.

The Cinco Minas Co.'s property was attacked by bandits on May 29, but the guard succeeded in driving them off after a four hours' battle with no loss of life to the mine. Two or three of the attacking party were killed or badly wounded, and furnished food for the not overfed razorbacks of the camp.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

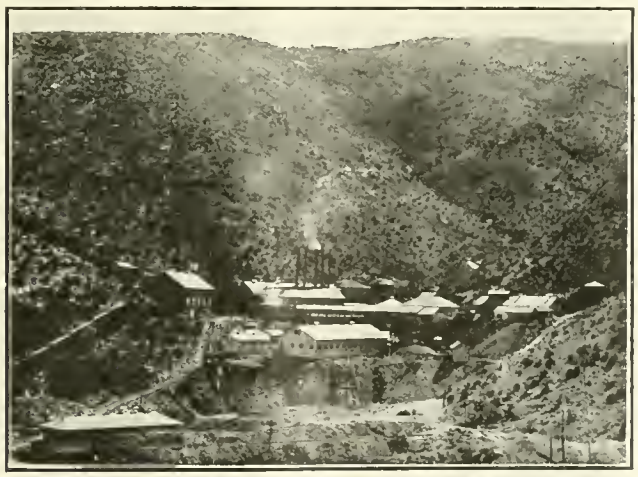
KNIK

The estimated gold production from quartz in the Willow Creek district for the 90-day season is $500,000, a good increase. There are 150 miners employed. The Mabel company has erected a mill. The Yago and Matanuska companies are developing their properties extensively. In 1915 the Gold Bullion yielded $132,000, Martin $150,000, and Independence $50,000. The Willow Creek Mines Co. has been formed to operate in the district. It has a lease on the Gold Bullion. Willow Creek will soon be served by the new railway from Anchorage.

ARIZONA

COCHISE COUNTY

During May the Shattuck-Arizona produced 1,383,963 lb. of copper, 25,865 oz. of silver, and 326 oz. of gold. No lead output was reported. The lead yield varies, the first four months of the year giving 267,853, 499,155, 714,379, and 130,570 lb., respectively. A dividend of 50c. plus an extra of 75c. per share has been declared.



SHATTUCK-ARIZONA MINE AT BISBEE.

GILA COUNTY

Twenty-five miles south of Globe steady development is under way at the Troy copper claims, owned by the Troy Arizona Copper Co. of Boston and New York. R. G. Mead is supervising exploration. Prospects are fairly good. The same people have bonded the Cane Springs gold claims, two miles south.

MOHAVE COUNTY

The Desert Power Co., whose lines end at Golconda, are being extended to Chloride, a distance of 8 miles.

If the Minnesota-Conner mine in the Wallapai district can be financed, another good producer would be added to the list. Past outputs total over $1,000,000 from a depth of 700 ft. The mine is idle, but is kept dry by bailing and pumping. P. S. Virgin is in charge of this gold-silver-lead property, which is well equipped.

Ten miles from Chloride the Arizona Butte Mines Co. is working several mines. An aerial tram at the Banner is availfor carrying ore from the group. As no treatment plant was near-by the mines were not worked for several years. Past production is said to be considerable, and a good deal of ore is available. Henry M. Crowther is in charge.

The Kingman Zinc Co. is producing concentrate regularly at the Cupel mill.——The Golconda Annex is shipping ore, which contains more lead than zinc.——High-grade gold, silver, and zinc ore has been opened in the Cerbat mine, and extraction is to commence soon.

Developments at 400 ft. in the Pioneer at Oatman are exciting attention, as for a length of 25 ft. there has been opened 8 ft. of ore worth $16 per ton. The new big mines with possibilities are the Big Jim, Pioneer, and United Eastern, and the old producers, the Gold Road and Tom Reed.

CALIFORNIA

Since the Workmen's Compensation, Insurance, and Safety Act became effective on January 1, 1914, up to and including the 31st of May, 1916, the Industrial Accident Commission has decided 2240 cases (exclusive of thousands of controversies adjusted without the necessity of formal hearings). Of this number there have been appealed to the Supreme Court and the District Courts of Appeal, 88 cases, leaving 2152 decisions of the Commission from which no appeals were taken, but which decisions were accepted by the parties as final and conclusive as to the law and facts. Of the 88 cases appealed, writs of review were denied in 26, and the decision of the Commission was affirmed in 6, making a total of 32 in which the decisions of the Commission were sustained by the Appellate Courts. Of the 88 cases appealed the decisions of the Commission were reversed in 13. Four of these 13 involved but two issues, so that the Commission was actually reversed in only 11 instances as to issue presented on appeal. This means that the decisions of the Commission had been sustained in practically two-thirds of the appealed cases, and that the Commission had been reversed in less than ½ of 1% of the cases decided by it.

AMADOR COUNTY

The Plymouth Consolidated reports as follows for May:

Ore milled, tons	11,780
Total value	$59,000
Working expenses	29,124
Development charges	6,929
Surplus	$22,947
Other expenditure	$ 2,787

BUTTE COUNTY

Old dredge and mill tailing on Butte creek, near Chico, between the Pacific Gold Dredging Co.'s land to the boundary of the United States Plant Introduction Gardens, an area of 336 acres, is being sampled for probable re-treatment. C. F. Helman, well known at Oroville, and O. W. Kay of Chico are making tests.

CALAVERAS COUNTY

At 1600 ft. in the Gold Cliff mine of the Utica company at Angels a narrow vein of very rich gold ore has been opened. Specimen ore is extracted freely.

Eldorado County

San Francisco capital has been interested in a number of claims in the Greenwood district. Development is in progress at the Argonaut, Greenwood, Seam, Belt, Bunker Hill copper near Penobscot, and Cedarburg near Spanish Dry Diggings. The last named has been idle for 35 years.

Inyo County

(Special Correspondence.)—A long, wide, and high-grade deposit of tungsten ore has been located 3½ miles south-west of Mt. Montgomery, Nevada, by A. Stevens and G. McClelland. This part of the country is in one of the oldest mining districts of Nevada.

Laws, California, June 15.

Sierra County

A consolidation of the Slate Creek, Sierra Union, Scales and Hounds Flat, and other hydraulic mines near Downieville has been completed by a company headed by F. R. Ritchie of San Francisco. The properties were examined by Karl Brehme. To allow of sluicing being done permission will have to be obtained from the Debris Commission.

Siskiyou County

News from Gazelle states that the Davis gold mine is being sampled. F. Chastain and others are shipping chrome ore,

SISKIYOU COUNTY, CALIFORNIA.

and the Polar Bear has made a trial shipment of copper ore. A custom plant may be erected near Gazelle.

Tuolumne County

(Special Correspondence.)—All the new machinery has been installed at the McAlpine mine, which is in charge of W. A. Irwin, at one time at the Standard mine at Bodie and the Associated mine at Kalgoorlie, Western Australia. Driving has been started from the 500-ft. level to get under the rich shoot worked years ago.

Coulterville, June 9.

COLORADO

Clear Creek County

(Special Correspondence.)—The Mid Colorado Mines Co. shipped 25 tons of concentrate running 40.875% zinc. Charles Lancaster is manager.

At the McClellan mine, a 6-in. vein is being opened, assaying 364 oz. silver and 6.75% copper.

The manager of the Josephine mine at Silver Plume, A. L. Stevens, shipped 66 tons of lead ore that netted $4100. Twelve men are stoping.

Re-timbering of the Doric adit has been completed by the Onondaga Mines Co. The adit is now in a distance of 3009 ft. from its portal. The manager, Tallmadge Kyner, will probably drive ahead and let leases on some of the many lodes already intersected. For this work a larger compressor and ventilating fan should be installed and perhaps the old plant changed from steam to electricity.

On the 100 ft. level of the Onondaga mine 4 ft. of ore is now being driven on, and a carload is shipped to the Hudson mill at Idaho Springs each day.

The manager of the Capital mine, E. Hamman, is increasing production in both quantity and quality, the only hindrance to a much larger output being ventilation.

Georgetown, June 13.

Lake County (Leadville)

Routine work continues at the Harvard, Penrose, and Wolftone pumping shafts. The first is almost unwatered.

At the Mikado shaft on Iron hill, 1206 ft. deep, and full of water to the 800-ft. level, extensive preparations are under way for drainage, re-timbering, and subsequent exploration. G. O. Argall of the Iron Silver company is in charge. A new 60-ft. head-frame is being constructed. A large hoist has been ordered, also pumps. The ground includes several well-known claims, and large bodies of lead-silver ore are expected to be opened.

From the Hugh lease in south Evans gulch the weekly output is 50 tons of $20 gold ore.

IDAHO

Attention of Eastern investors is being turned to the acquisition and development of gold properties in central Idaho to an extent previously unknown in the region. Many of the camps were the scenes of some of the earliest gold rushes in the North-west, according to Henry Massam, pioneer mining operator, manager of the Idaho National company's placer holdings and the Mascot quartz mine, near Elk City. The entire central Idaho district is more active than for years, and a number of properties that have been idle and practically abandoned are to be developed. Small mills are being erected at different points in the Elk City-Newsome-Ten-Mile and other centres, and there is every reason to anticipate that the output this summer will establish a new high record.

Idaho County

Four men operating a one-stamp (450 lb.) mill, which they dragged in over the snow last April, are extracting from $40 to $50 per day from the Lone Yellow Pine mine on Ten-Mile, 45 miles south and east of Stites. The property is owned by John Harmon and Doit Morrow. The battery is driven by an over-shot water-wheel. In the same district Smith brothers have 5 stamps on the New York claims. Last winter the yield was $21,000. The Orient company is extracting $7 per ton by amalgamation.

Shoshone County (Coeur d'Alene)

Railroad connection between Wallace and the Beaver Creek district is considered necessary. The Ray-Jefferson and Interstate Callahan would then have a better outlet, also the entire Sunset region. The Northern Pacific line is expected to do something in the matter.

The west side of Nine Mile is one of possibilities judging by recent transactions and new development. On the east side are the Interstate-Callahan, Tamarack & Custer, Success, Rex, and Patuxent.

According to the *Wallace Miner*, leasing has come to be an important feature of mining operations in the Coeur d'Alene district. It was at first mostly limited to leasing old workings and to blocks of ground that could not be profitably mined by large operating companies, but which offered good pay to practical miners who devoted their own time to the work and who exercised more care in separating the ore from waste. Then there are small and rich veins which apparently did not justify a large expenditure for equipment, which have yielded handsome profits to practical miners under lease. Gradually the leasing system has been growing in popular favor, and in

the Wardner district particularly some valuable leases have been secured which yield large profits.

Reports are current at Kellogg that operations will soon begin on the 1200-ton mill for the Interstate-Callahan company on the site secured some months ago at Enaville.

Several parties are said to be considering a deal on the old Butler silver mine, near Wardner, and a resumption of operations may be expected at an early date. The property has been idle for 20 years.

During May the Interstate-Callahan company mined 12,801 tons of ore, which produced 540 tons of concentrate containing 54% lead, and 10,080 oz. silver, also 6146 tons of concentrate averaging 49.8% zinc. The mill recovery was 90.5%, and smelter returns were $440,089. The three-compartment shaft from the main adit of the Interstate-Callahan workings was sunk 405 ft. in May, and connection has been made with the Amazon-Manhattan group adjoining, acquired several months ago by the company. The shaft will be sunk still farther, to connect with the 600-ft. adit of the Amazon-Manhattan, which is being advanced to meet it.

MICHIGAN

The Copper Country

Some of the tonnages of ore reported during May were as follows: Ahmeek, 110,000; Tamarack, 40,000; Wolverine, 41,000; Calumet & Hecla, 300,000; Quincy, 102,600; Wolverine, 31,100; Franklin, 24,000; Centennial, 14,000; Allouez, 47,200; La Salle, 12,500; Superior, 18,200; Mass, 31,200; and Hancock, 11,600 tons.

An editorial in a recent issue of the *Daily Mining Gazette*, Houghton, has the following:

"The equalization committee of the board of supervisors of Houghton county agreed last week to raise the valuation of the county approximately $10,000,000. It means substantial increases in taxation. More than that, the committee, at the suggestion of the largest tax-paying interest in the county, decided that this additional valuation should be placed on the copper mines, so that the additional taxes will fall on the mining corporations and not on the other property owners in the county. It is fair and just and right. But did you ever hear of any board of supervisors in this whole State voluntarily agreeing to increase their own taxes? Increases usually come when they are forced by State officials. And did you ever hear of a board of supervisors' equalization committee practically placing a $10,000,000 increase in valuation on the property which they themselves control and manage? It is a record in the history of politics in this State. And it is right in line with Houghton county's reputation for fairness. The facts are that the increase in valuation in this county has, in reality, come to the mining corporations. But it has, nevertheless, some effect on other property. Next year it will have a further effect on other property. But this action by the committee is entitled to commendation. It is, of course, the informal session of the committee. The figures on mine valuation have to be approved later at a formal session and then endorsed by the board of supervisors as a whole. But in the past these informal agreements on mine valuation always have stood up and the agreement at the equalization committee was unopposed."

MISSOURI

Jasper County (Joplin District)

On June 19 rain amounting to 5.75 in. fell at Joplin, flooding the town and mines, stopping ore extraction for some days.

In the week ended June 11 the ore market remained firm. The Missouri-Kansas-Oklahoma region produced 6348 tons of blende, 129 tons of calamine, and 950 tons of lead, averaging $77, $55, and $81 per ton, respectively. The total value was $577,200; and for 23 weeks, $18,792,175.

North-east of Webb City the Rollamo company has a tailing-plant treating dumps. About 1200 tons is treated in three 8-hour shifts, in two rougher, one chat, and one cleaner jig. In one day of 24 hours the mill produced 18 tons of concentrate, and in one week 90 tons. This product contains 57.6% zinc, 0.25% lead, and 1.2% iron. Ten sludge-tables are to be added. The motive power is a 150-hp. gas engine. The Millers and White of Joplin are owners.

MONTANA

Beaverhead County

A small boom has started at Bannack due to renewed activity in old and new mines.

Fergus County

During May the Barnes-King company's mines produced 3779 tons of $7.41 and 2178 tons of $4.59 ore, both increases compared with April. New construction continues.

Mineral County

Crude copper ore, fine and jig concentrates (from its 100-ton mill) are averaging $25, $50, and $75 per ton, respectively, from the Amador mine near Superior. The mine is opened to 700 ft., with good reserves. The mill commenced work in May. Oscar Nordquist is manager.

Silverbow County

All the Anaconda mines are working at full capacity, making the power-demand so heavy that at the High Ore steam hoisting has replaced compressed air, which is used at most of the mines. The High Ore is 3600 ft. deep, and is a large producer.

In the near future the Butte & Great Falls company is to sink another shaft to a depth of 1000 ft. The cross-cut being driven south from the shaft is in 575 ft. on its way to the Dewey vein. At 460 ft. the Genevieve vein was cut, showing 11 ft. of good copper-silver-gold ore.

At 1600 ft. in the Butte & London a large station is being cut. Some highly mineralized rock has been disclosed by this work.

Foundations are being prepared for the new hoist at the Davis-Daly.

The strike of various trades at Butte is over.

NEVADA

Churchill County

At Wonder the Goldfield Oro company is to resume work at its Vulture mine, adjoining the Nevada Wonder. Exploration will start at 800 ft., in charge of T. F. Manning.

Esmeralda County

During May the Jumbo Extension produced 2850 tons of ore worth $91,500. Charges were $17,500 for mining, $32,250 for freight, sampling, and treatment, and $10,500 smelting losses, leaving $31,250 net. This profit is $6000 above that in April, and $10,000 in March. Shipments are now 150 tons daily. Some $8 dump ore is being marketed.

Development at the Florence is improving, new ground at 650 ft. being of promise. Additions to the flotation plant will be ready by the end of June.

At the Silver Pick the shaft is being sunk rapidly from 700 to 1000 ft. depth.

In the Lida district, south-west of Goldfield, the Florida claims have been purchased by the Theo brothers of Goldfield for $45,000. A flotation plant is to be erected to treat the ore and that from their mine at Hornsilver.

Lyon County

(Special Correspondence.)—The leaching-plant of the Nevada-Douglas company at Ludwig has been placed in operation, treating 250 tons of ore daily. It is probable a larger quantity will be put through as the various units reach ca-

pacity. Fuel oil is used in the furnaces. The management recently announced that a large tonnage of good-grade ore was available.

The Yerington Mountain company, operating near Schurz, is shipping 12 to 20 tons of copper ore per day. A cross-cut from the Levine winze has cut the vein, showing a width of 5½ ft. Two feet of shipping ore is exposed in the intermediate level of the Beach workings. John G. Kirchen of Tonopah is general manager.

The Reservation Hill district continues to report progress. On the 200-ft. level of the Mountain View the vein is said to be over 30 ft. wide, with much of this of good milling grade. The mill is running steadily, using water from the Walker river. An option has been taken on the Pack Saddle group by Colorado people, and preparations are being made for extensive work.

Yerington, June 7.

NYE COUNTY

From March 9 to May 31 the Round Mountain hydraulic plant moved 106,600 cu. yd. of gravel, yielding $40,000, with no clean-up of bedrock.

Ten mines at Tonopah last week produced 9937 tons of ore valued at $186,126. During May the Belmont's yield was 229,351 oz. of bullion from 12,824 tons of ore, giving a profit of $126,263. From 3153 tons the Jim Butler's profit was $23,361. The Tonopah company treated 9239 tons for a profit of $26,330. Only 125,000 oz. was shipped.

WHITE PINE COUNTY

(Special Correspondence.)—It is announced by wire from action taken at recent annual meeting of the Consolidated Coppermines (old Giroux) Co. at Delaware, that it has been financed to the extent of $100,000. The old mill at Pilot Knob will be overhauled to treat 500 tons per day, including flotation. Also arrangements have been made with the Nevada Consolidated to mine from the Coppermines Oro claim in Liberty pit 1000 tons daily, and treat it at the plant at McGill.

The Nevada Consolidated has under way a drilling campaign. During April 8500 ft. was drilled, which in some instances showed 4% copper ore. It is understood that there is 500 ft. depth of ore in the bottom of Eureka pit, as shown by drill-holes. The general public appears to think that the Nevada Consolidated is a surface deposit only.

Tungsten activity has somewhat subsided owing to the drop in price and no market. The U. S. Tungsten Co. has reduced its mill to one shift for want of ore. It has a contract at $72.50 per unit. Much ore of commercial grade could be purchased, helping themselves and the prospector.——The Independent mill was started and made a short run, but has not sufficient power for the crusher and elevators.——The Consolidated Tungsten Co. adjoining the U. S. T. Co. on the south has its mill running.——The Nevada Scheelite Co. (Minerva district) has a small plant in operation for sampling purposes.

Ely, June 10.

High-grade zinc ore has been found by the Lead King company in the Dock Creek district, 1½ miles east of McGill. A good deal of development has been done.

OKLAHOMA

OTTAWA COUNTY

For the sum of $125,000 the U. S. Smelting Co. has purchased 60 acres of land from B. H. Marbury, north of Cardin. The lease calls for a 6% royalty to be paid to the Indian landowners. A mill at the Ravenswood mine at Reeds, Missouri, will be moved to the new property.

UTAH

There is a congestion of ore at the smelters in this State, and temporary curtailment of production has been notified to companies, especially lead-silver producers.

The Utah Ore Sampling Co. is to erect another plant at Murray. At present 500 tons daily is handled. This company has samplers at full capacity at Park City and Silver City.

JUAB COUNTY

During May the Iron Blossom earned $40,000. The copper ore mined at 1100 ft. is expected to be cut at 1700 feet.

SALT LAKE COUNTY

High-grade ore, 10 ft. wide, has been cut at 2100 ft. in the Quincy adit of the South Hecla in the Little Cottonwood district.

WASHINGTON

FERRY COUNTY

Plans are under consideration by the Northwestern Development Co., a recently organized Spokane corporation, to convert the old smelter at Keller into an electro-chemical plant for the treatment of ores of the Keller-Nespelem region. The smelter was built seven years ago, when it was anticipated that the Colville Indian reservation would be opened and a railway constructed into the district, but the furnaces never have been blown-in. The plant, including the electric-power station, cost $250,000, and it is said to be in excellent condition still, having been well cared for. It is provided with facilities for treating 100 tons of copper ore and 50 tons of lead ore daily. The property was taken over several months ago by the Northwestern company, which at the same time acquired the Manila and Rebecca groups of copper-lead-silver claims near-by. If the plant is operated as suggested, it will necessitate changes in the equipment that will cost not less than $70,000, but it will obviate the shipment into the camp of expensive coke. There are plenty of good properties to supply a smelter in that locality. The Iron Creek Mining Co. is hauling ore 56 miles to Republic, and shipping it to the smelters. This ore contains 600 oz. silver and 16% lead. The Walla Walla Copper Co. is working three shifts, and has a large body of high-grade copper ore. The Summit mine has ore in considerable quantities. The Manila has as large a body of copper ore, and only needs transportation facilities. It is 435 ft. wide, as shown by diamond-drill prospecting, and carries 1.83% copper. William E. Malm is one of the chief stockholders and manager, with William E. Johnson as superintendent.

WYOMING

The State Geological Survey at Cheyenne, L. W. Trumbull in charge, has issued a new map of the State. It is 35 by 46 in., and shows contours and important centres. The map is for sale at $1.

Production of coal in Wyoming in 1915 was 6,554,028 short tons, an increase of 78,735 tons, or more than 1% as compared with 1914, according to figures compiled by C. E. Lesher, of the U. S. Geological Survey. The total value decreased nearly 5% from $10,033,747 in 1914 to $9,555,804 in 1915. The number of men employed in the coal mines decreased from 8117 in 1914 to 7244 in 1915, but the average number of days worked increased from 192 to 201.

CANADA

BRITISH COLUMBIA

Some attention has been attracted to the Blue Bell peninsula on the east side of Kootenay lake, almost opposite Ainsworth, by the recent opening of a large surface showing of galena on the Comfort claim owned by A. D. Wheeler of Ainsworth. Hudson Bay trappers, 60 years ago, made bullets from this lead ore.

According to Ernest Levy, manager of the Le Roi No. 2 mine at Rossland (which is primarily a gold district), the cost of explosives and other supplies are high, a 30 to 50% advance, and wages are up 16%, the whole making conditions undesirable, as there are no benefits from high prices for the product.

ONTARIO

The Nipissing in May produced silver worth $291,898, against $124,452 in April. Bullion shipments, including custom ore, totaled $420,822, equal to 558,148 oz. Vein 490 contributed largely. Shaft No. 81, to explore the Cobalt Lake vein, is down 550 feet.

The 150-ton flotation annex is working well at the McKinley-Darragh. It treats tailing from the tables.

The Dome in May produced 39,400 tons of ore averaging $4.79 gold per ton. The cost was $2.46 per ton. The grade is 55c. higher, and cost an increase of 15 cents.

MEXICO

On account of probable trouble between Mexico and the United States, American employees are leaving Cananea and Nacozari. Those at El Tigre are not coming out yet.

Mining in Warfare

A metallurgist, well known in San Francisco, and now an officer in the engineering corps of the Italian army, writes as follows to a friend in California:

"The job is done. On the 12th of January I started drifting toward the enemy's lines on top of the Col di Lana, at 2464 metres above sea-level. It was a long drive of over 300 ft. At the beginning of April we were under their lines; the enemy found us out and began to counter-mine. On the 7th the enemy shot its first counter-mine; an officer and five men were buried by a cave, but nobody was seriously hurt. Half an hour after we were again at work, blasting six rounds per day without stopping work day or night. The enemy went again after us, nicking three shafts, and driving right and left. On the 9th I stopped all work and the enemy kept working as hard as he could. One drift was right over our heads, and we could hear the Austrians walk and the rock tremble under the blows of the pick. We kept perfect silence, waiting until the infantry should be ready. On the night of the 15th the enemy was so close that I decided not to delay further. From 10 p.m. to 7 a.m. we loaded 10,040 pounds of gelatine and 92% nitro-glycerine. By noon of the 17th the mines were tamped.

"At 11:35 p.m. of April 17 everybody moved silently to his appointed place; the trenches were deserted. We officer-engineers sat on the floor of a gallery, our hands on the ropes of the little generator. At the very second appointed we pulled. The earth trembled as with an earthquake, but the explosion was not very loud. After two or three seconds came the shower, or rather, heavenly earth-slide; some 15,000 tons of rock and earth, burying everything under itself, even our own trenches, and almost our galleries.

"The moon was at full. The sky was clear. At the instant of the explosion, all the batteries on the mountain around us opened an infernal fire on the top of the mountain. It was an incredibly fantastic sight.

"The Italian 'tommies' poured out from the galleries and stormed the top 300 ft. distant. The famous Col di Lana was ours at last! I waved the flag on the very top, and all the soldiers with me shouted "Viva l'Italia." At my feet was the crater, some 90 by 150 ft. in oval, and about 35 ft. deep. Everything broken, scattered, mashed, and destroyed. The wire entanglement was buried under thousands of tons of rock. Some 80 Austrians were blown out of existence; we captured 170 prisoners, 9 officers, one gun, etc. The victory was ours."

The UNIVERSITY OF NEVADA at Reno has issued its catalogue for 1915-'16, with announcements for 1916-'17. The publication covers 254 pages, and discusses all phases of the college activities. Lectures for the new semester commence on August 30.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

ROBERT T. HILL is at Washington.

PAUL W. AVERY is here from El Oro.

C. E. RHODES has left El Oro and is now at Los Angeles.

S. S. LANGLEY, of Los Angeles, was here during the week.

BENJAMIN GONZALEZ sailed on the *Colusa* on June 15 for Salvador.

VICTOR G. HILLS, of Denver, sailed from here to Honolulu on June 21.

ARTHUR W. STEVENS was recently at Idaho Springs, Colorado, and is now in Utah.

WILBUR H. GRANT has been examining copper mines in Humboldt county, California.

HENRY KRUMB, who has been inspecting the Braden mine in Chile, has returned to New York.

C. H. MACNUTT, manager for the Burma Mines Co., is at the Fairmont hotel. He has resigned.

W. G. MATTESON is doing geological work for the Empire Gas & Fuel Co. of Bartlesville, Oklahoma.

ROBERT E. CRANSTON is examining the Lucky Girl mine in the Edgemont district, near Elko, Nevada.

ROY A. SULLIGER has been appointed mill superintendent of the Minas del Tajo, Rosario, Sinaloa, Mexico.

EDMUND SHAW, until recently metallurgist at the La Leonesa mine in Nicaragua, has returned to El Paso, Texas.

C. T. SOKUP has left the Canadian Copper Co. to take a position with the American Smelting & Refining Co. at Kansas City.

RICHARD C. MCINTYRE has received an appointment on the staff of the Burma Mines, and sails from San Francisco to Rangoon early in July.

COREY C. BRAYTON and E. R. RICHARDS have opened offices in the Hobart building, San Francisco, to conduct the business of mining and metallurgical engineering.

F. W. TRAPHAGEN, professor of metallurgy in the Colorado School of Mines, has resigned to accept the presidency of the Colorado Metal Mining & Reduction Company.

J. A. FORCE, who has been in charge of operations for the Consolidated Mines & Reduction Co. at Cripple Creek, has resigned. He intends to devote his time to private practice.

THE EDITOR will be grateful for occasional good photographs of subjects relating to mining and metallurgical operations. They should be printed on glossy paper.

The 19th annual session of the American Mining Congress will be held at the LaSalle Hotel, Chicago, Illinois, during the week of November 13.

At the Commencement of the University of Illinois on June 14, 222 baccalaureate degrees were granted to students of the College of Engineering, of which 39 were civil, 43 electrical, 44 mechanical, and 3 mining engineers.

The U. S. Civil Service Commission announces an open competitive examination for coal-mining engineer, for the Bureau of Mines at a salary ranging from $2400 to $4000 per annum. Applications must be filed with the Commission at Washington, D. C., by July 18. There will also be an examination for assistant petroleum engineer for the Bureau of Mines, at a salary ranging from $1800 to $2500 per annum. Applications must be filed by July 18.

THE METAL MARKET

METAL PRICES

San Francisco, June 20

Antimony, cents per pound	37.50
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	7.25—8.25
Platinum, soft metal, per ounce	75
Platinum, hard metal, 10% iridium, per ounce	$79
Quicksilver, per flask of 75 lb	$68
Spelter, cents per pound	21
Tin, cents per pound	15
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, June 20.

Antimony 50% product, per unit (1% or 20 lb.)	$1.25
Chrome, 40% and over, f.o.b. cars California, per ton	12.00—14.00
Manganese 50% product, f.o.b. cars California, ton	20.00
Magnesite, crude, per ton	7.00—10.00
Tungsten, 60% WO_3, per unit	30.00—40.00

The tungsten situation at Boulder, Colorado, is unchanged.

Fluorspar bulletin of the U. S. Geological Survey has been issued. The output last year was 136,911 tons worth $5.58 per ton.

Bauxite (aluminum ore) production of the United States in 1915 was 297,041 tons, averaging $5.14 per ton.

New York, June 14.

Antimony: Prompt delivery ore has sold at $2.50 per unit, but the demand is light.

Tungsten: A broker quotes $32 to $36 for material running 65% and over, while a buyer says that as low as $30 has been done recently. The buyer does not look for much higher prices, his opinion being that production has been overdone. There no longer is such frantic buying of high-speed steel as existed a few months ago, and this has eased the demand for ferrotungsten. It is hoped that some foreign inquiry for tungsten will materialize, but in this connection it is to be remembered that England is forging ahead in the manufacture of ferrotungsten, using ores from Burma and Portugal. The material has been quoted lower in England than in the United States.

EASTERN METAL MARKET

(By wire from New York.)

June 20.—Copper is dull and weak, lead is quiet though steadier; spelter is stagnant.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
June 14	63.00	May 9	75.89
" 15	62.87	" 16	76.40
" 16	63.12	" 23	74.14
" 17	63.87	" 31	70.81
" 18 Sunday		June 6	66.35
" 19	64.75	" 13	64.58
" 20	64.12	" 20	63.62

Monthly averages

	1914.	1915.	1916.		1914.	1915.	1916.
Jan.	57.58	48.85	56.76	July	54.90	47.52	....
Feb.	57.53	48.45	56.74	Aug.	54.35	47.11	....
Mch.	58.01	50.61	57.89	Sept.	53.75	48.77	....
Apr.	58.52	50.25	64.37	Oct.	51.12	49.10	....
May	58.21	49.87	74.27	Nov.	49.12	51.88	....
June	56.43	49.03	....	Dec.	49.27	55.34	....

The current week has witnessed fluctuations in silver, but nothing termed violent, the tendency being upward. Samuel Montagu & Co. of London say that it is impossible to overlook the fact that the statistical position of the metal is extremely strong—the amount of the nominal stock in London available for sale is but a mere fraction of the total. There is no reason to believe that hoarding of silver has yet taken place in America, at any rate to any important extent. The heavy expenses of freight and insurance tend to retard, if not to deter, exports from India.

Silver reserves of the Tonopah Belmont on May 1 amounted to 1,150,000 oz. Recent sales were 100,000 at 71c., and 200,000 oz. at 76c. A 12½c. dividend has been declared.

Eastern Metal Market

New York, June 14.

What is the matter with the metal market? This is an inquiry heard on many sides. Briefly, there has been a reaction, in some cases, violent, in every metal with the exception of aluminum.

As bearing on the question, two or three points may be made. One is that the warring nations are buying more carefully and skillfully than they did a few months ago, when the cry was, give us the stuff, whatever the price. Today the suspicion exists that Great Britain is in various ways endeavoring to depress American prices in order to make her purchases more favorable to her interests. This seems to be true particularly of brass and copper-finished products, such as rods, sheets, and billets. Foreign buyers have spurned American bids in some cases, on the ground that they can buy cheaper at home.

Another point is that domestic consumers are not only cautious in their buying, but are being urged by at least one large mill to exercise still greater conservatism in buying for the future. They are told that orders cannot be cancelled; that the end of the War will bring lower prices, and that the mill in question prefers small orders sufficient to meet current demands. This attitude on the part of a mill may seem odd, but it actually exists.

Copper, zinc, lead, and tin are dull, and lower in price. Antimony is demoralized. It seems that a re-adjustment of prices is under way. But even if this is true, and lower prices are to prevail, they will unquestionably be above normal, and big profits will continue to be made.

COPPER

The market has continued dull, with scarcely enough doing to test prices. The producers are booking little or no business, and second-hands are having things their own way. That the producers are well sold-up has been repeatedly stated. For the forward positions (from September on) their quotations are understood to range from 29 to 29.75c. There is plenty of re-sale copper to be had, however, this side of September, in fact, near-by deliveries of electrolytic are procurable at 27.75 to 28c., cash, New York, and small quantities probably could be picked-up lower. The demand is so light that all quotations are nominal. Lake is nominally quoted at about 28c., but the demand for it is light also. Rumors that London was contemplating some good buying have been current, but they are unsubstantiated. The London market is quiet at £141. The feeling is widespread that the general dullness of the market can be attributed in part to Great Britain's desire to depress prices for her own benefit. A statement of this kind is difficult, if not impossible to prove, but some facts stand out strongly. It is admitted by members of the trade that the day is past when England will pay premium prices for copper or brass and copper products if she can avoid it. In several cases where quotations have been submitted on brass rods and billets, on copper sheets and other finished products, the answer has come that the intending buyers could do better at home. One house, on this ground sought to cancel an order for 15,000 tons of copper sheets; another said it could save 5c. per pound on brass billets by buying at home. It is conceded that before business in these products can reach larger proportions, the London prices must be met. The mills are so well filled with orders that so far they have declined to do this. The condition is not conducive to extending the export business. On the other hand, domestic manufacturers continue their policy to buy sparingly, or only to cover new contracts. In some cases where they have sought to buy ahead, certain mills have emphatically stated that any orders they might take would not be subject to cancellation; they also pointed out that prices would collapse with the end of the War, and that consumers might well proceed cautiously in providing for their future needs. Exports of ingot copper, June 1 to 14, totaled 14,057 tons.

ZINC

Some doubt was expressed a week ago as to whether the improvement then noted would hold. Since then the bottom has dropped out of the market. Quotations are again on the downgrade and yesterday near-by metal could have been had easily at 14.50c., New York, or 14.25c., St. Louis. July is quoted at about 13c., St. Louis, September at 12c., and October at 11.50c. It is certain that, though the recent movement was a short one, a large amount of zinc was contracted for, not a little of it by galvanizers. The London market is weak, and yesterday it declined £2 to £68 for prompt. The drop abroad was a further depressing influence on this market, and made sellers all the more anxious to move their holdings. Not since last October has the London price been so low. Exports, June 1 to 14, totaled 2065 tons.

Sheet-zinc has been reduced to 20c., f.o.b. mill, carload lots.

LEAD

The common story applies to lead—a weak, sagging market, with outsiders making the low price. The A. S & R. Co. continues to quote 7c., New York, and 6.92½c., St. Louis, as prices at which it will sell (not merely bases for averages), but the Independents are quoting down to 6.85c., New York, and there is little doubt about their willingness to accept 6.80c., New York. The London quotation is off a few points, and stood yesterday at £31 5s. Exports June 1 to 14 totaled 1152 tons. Features of interest are lacking.

TIN

No interest on the part of consumers, and lower prices, sums up the situation. Not only has there been no business worthy of note, but each concession designed to arouse the buyer has only made him more shy. It now develops that there was very little real need for the alarm felt over the question of obtaining British shipping licenses. For months the market has been supported by reports that Great Britain was likely to halt the issuance of licenses, thereby creating a shortage of tin in this country. Not only has such action not been taken, but Banca tin, acceptable for many purposes has been coming here freely. It is not subject to any license restrictions, and has been selling at ¾ to 1c. below the price of Straits tin. While its use is broader than formerly, the tin-plate manufacturers stick to the use of Straits. The A. S. & R. Co. is distributing moderate-sized lots of the tin it refines from Bolivian ores, and it is good-looking stuff. Spot Straits tin was quoted yesterday at 43.25c. at New York. Arrivals this month total 2510 tons, and there is afloat 3102 tons.

ANTIMONY

Whereas Chinese and Japanese grades were quoted a few months ago at 45c., they are now to be had at 20c., duty paid. One seller asserts that it would be wrong to say that there is any market at all, and others agree with him. One theory for the absence of demand is that antimony is no longer called for as a hardener in shrapnel bullets, the making of shrapnel having given way to the manufacture of high-explosive shells. There probably is some truth in this statement, but it does not entirely explain the situation.

Price of Scrap Metals

A wide range of prices is being quoted for all scrap metals at New York, the market being largely a matter of individual outlet, which is of a routine character, according to the *Daily Metal Reporter*. The divergence of views as to new copper prices that exist between producers and some of the second-hands, is reflected in the market for copper scrap, and there is a correspondingly wide latitude between ideas of scrap-metal specialists on copper. The downward revision in lead values is discernible in a marginal reduction in heavy scrap-lead. Uncertainty in the spelter situation makes for an easier tone in scrap and new zinc. Some prices are as follows in cents per pound:

Crucible copper	22.50—
Heavy copper and wire	22.00—
Light copper	19.00—
Heavy yellow brass	12.50—13.00
Clean light brass	10½— 11
New brass clippings	15 — 15½
No. 1 composition	17 —
No. 1 composition turnings	15 — 15½
Yellow brass turnings	12½— 13
Red car boxes	14½— 15½
Cocks and faucets	15 —
Heavy lead	5½—
Tea-lead	4½— 4¾
Scrap-zinc	9 — 9½
New zinc-clips	10 — 10½
No. 1 pewter (nominal)	30 —
Siphon tops (nominal)	28 — 29
Block tin pipe (nominal)	38 — 40
Tin-foil (nominal)	26 — 27
Solder joints (nominal)	9 —
Cast aluminum	35 — 36
New aluminum clippings	47 — 50
Aluminum borings and turnings	22 — 23
Electrotype (nominal)	5 — 5½
Stereotype (nominal)	7½— 8

Copper and the Decline in Metals

From its recent high price of 30¼ cents per lb., electrolytic copper has receded 3c. to 27¼c. for immediate delivery metal, or 10%. The copper shares with inexplicable timidity have failed to sell on a basis fully warranted by even 17-c. metal, and have fallen away a little over 6% from their best quotations, according to the *Boston News Bureau*.

The drop in all the major metals—pig-iron alone excepted—has greatly exceeded the reaction in copper, and yet their shares have in some instances responded not by a sympathetic decline, but by new high record figures.

The average selling price of electrolytic copper over the past 10 years has been 15c. per lb., a figure which has permitted a 50% manufacturing profit over the average cost (plus depreciation) of say 10c. per lb. In a great many cases, notably where there is a definitely determined tonnage of ore, the present stock-market valuations would be entirely justified with copper at only 13c. For instance, it is calculated that on 13-c. metal Inspiration could mine its known orebodies for 20 years, and return the investor at $45 per share all the money he had put into it, plus 6% interest, in the meanwhile. With copper averaged at 15c. the value of Inspiration jumps to $63.

Just why 'coppers' have never responded to the sensations of a 30-c. metal market is a complete mystery, unless the market leaders themselves under-estimated the war demand for copper and sold out their stocks when the metal reached 20c. If they are trying to get them back they have met with indifferent success. The public won't buy and won't sell!

In the case of spelter, the price of prime Western has been cut in halves from the top notch of 26½c., made in June, 1915, but spelter shares represented by a composite average of Butte & Superior and American Zinc have receded only 10%. From the high of the year prime Western is off 36%.

It is clear therefore that the copper shares, measured by the past, present, and future of the industry are in wonderfully strong position, and values must ultimately count.

Herewith are some interesting figures showing to what extent leading metals are off from their best prices of this year, all reduced to a per pound basis:

	High 1916	Present price	Decline	Decline %
Gold	$248.04	$248.04	....	...
Pig-iron	0.0092	0.0090	$0.0002	2.7
Aluminum	0.63	0.58	0.05	7.9
Copper	0.30½	0.27½	0.03	10.0
Silver	8.90	7.53	1.37	18.7
Lead	0.08½	0.06¾	1.75	20.0
Tin	0.57	0.44¾	0.12¼	21.5
Spelter	21.17	0.13½	7.67	36.3
Quicksilver	4.00	1.00	3.00	75.0
Average of 20 copper stocks	60.96	56.96	4.00	6.5
Zinc stocks*	101.43	90.05	10.93	10.7

*Composite of Butte & Superior and American Zinc.

Copper Dividends

The following table of quarterly dividend payments pictures in a graphic way how the copper shareholders' income has been increasing during the past 12 months, according to the *Boston News Bureau:*

	1916		1915	
	2nd quarter	1st quarter	2nd quarter	1st quarter
Ahmeek	$3.00	$3.00	$2.50	$0.75
Allouez	2.00	1.50	....	....

Utah Copper	3.00	2.50	1.00	0.75
*Wolverine	...	6.00	....	4.00

*Pays dividends semi-annually.

In spite of the fact that the metallic aluminum consumed in the United States in 1915 amounted to 99,806,000 lb., there was a great scarcity of the metal in this country, especially during the later part of the year, according to information gathered by W. C. Phalen, of the Geological Survey. A greatly increased demand, together with the curtailment of imports, were the chief causes of this scarcity. Applications of the metal have been many in the War in Europe.

COMPANY REPORTS

ALASKA MEXICAN GOLD MINING CO.
ALASKA TREADWELL GOLD MINING CO.
ALASKA UNITED GOLD MINING CO.

These three well-known companies, operating on Douglas island opposite Juneau in Alaska, are under the general superintendency of P. R. Bradley, and their reports for the year ended December 31, 1915, will be read with extra interest on account of the consolidation now under way. The best way to show the past year's results is by the followiug table:

			United	
Items of operation	Mexican	Treadwell	Ready Bullion	700-Ft. Mine
Men employed	121	718	276	
Average wage per day	$3.36	$3.61	$3.46	
Development in own mine, feet	2,153	7,284	1,865	....
Development in 700-Ft. Mine, feet	354	14	....	5,197
Central development and shaft, feet	*3,054	*3,054	.....	*3,054
Combination development and shaft, feet	*642	*642	.....	*642
Diamond-drilling, feet	158	171	.....	....
Work at No. 2 shaft, feet	....	....	4,551	....
Underground cost, per ton	$0.85	$0.7804	$0.8905	$0.9042
Mine samples, number	2,027	4,264	1,810	2,415
Average value per ton	$2.04	$2.21	$3.43	$2.48
Reserves in place, tons	965,024	6,611,571	2,288,590	4,801,333
Reserves broken in stopes, tons	223,842	401,184	294,515	92,575
Total reserves, tons	1,188,866	7,012,755	2,583,105	4,893,908
Average value per ton	$1.87	$2.28	$2.86	$1.75
Reserves in previous year, tons	688,738	7,159,253	2,144,062	2,542,477
Average value per ton	$2.68	$2.48	$2.85	$2.22
Stamps dropping	120	540	150	150
Duty per stamp-day, tons	5.24	4.8	5.64	5.25
Ore crushed, tons	216,428	900,211	252,154	283,514
Gold by amalgamation	$190,980	$936,092	$272,274	$263,319
Concentrate cyanided, tons	4,769	19,177	5,621	5,992
Gold from concentrate	$188,817	$892,361	$249,638	$256,943
Total recovery	$379,797	$1,828,744	$521,912	$520,263
Yield per ton	$1.7548	$2.0314	$2.0698	$1.8497
Cost of milling	$0.306	$0.3122	$0.2932	$0.2735
Operating cost per ton	$1.3000	$1.2333	$1.3054	$1.2973
Construction, etc., charges	$0.0966	$0.0407	.....	$0.0146
Total costs	$1.3966	$1.2740	$1.3054	$1.3119
Profit	$99,477	$859,187	$192,738	$151,254
Balance from 1914	$10,814	$48,680	$15,160	
Total available	$110,291	$907,467	$382,410	
Dividends paid	$90,000	$650,000	$252,280	
Depreciation	$10,101	$167,777	$94,115	
Balance for 1916	$10,190	$90,090	$36,015	

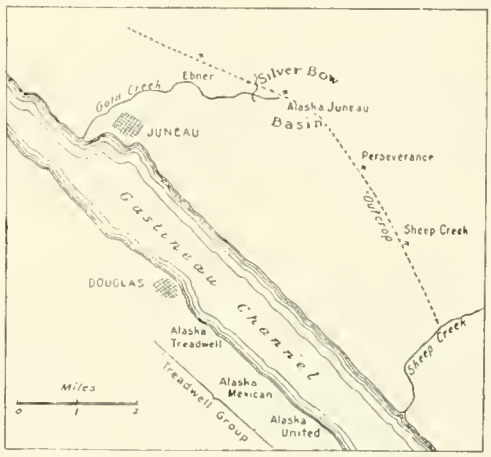
*Done jointly with the other companies.

Ore reserves are calculated to a depth of 2100 ft. in the Mexican and Treadwell, and 2200 and 2300 ft. in the Ready Bullion and 700-Ft. claim. The bottom levels in all show the greatest tonnages. As usual all companies contributed to the work at the Central shaft. This was sunk 117 ft. to a depth of 2471 ft. The main crank-shaft of the Central hoist broke in June, causing a tie-up of work here for 23 days. A new piece of shafting was joined to the other by a flange-coupling, with complete satisfaction. The Mexican No. 2 shaft is being enlarged to five compartments, and is now known as the Combination. When down to 2100 ft. this shaft will give a second means of access from the surface to the lower levels of the group.

The cyanide-plant treated 35,502 tons of concentrate from the five mills at a cost of $3.25 per ton of concentrate. The recovery was 97.03%.

The assay-office did 52,220 samples at a cost of 23.7c. each.

The Central power-plant (steam) has now a capacity of 4750 kw. Various additions and improvements were made to the hydro-electric plant, including a machine to act either as a generator or motor at the Treadwell 240-stamp mill, depending on the supply of water for its change from one to another.



SKETCH OF THE JUNEAU DISTRICT, ALASKA.

Work of the Treadwell Committee of Safety continued satisfactorily with a gradual broadening of its scope.

BROKEN HILL PROPRIETARY CO.

Iron and steel production is now one of the most important phases of this great Australian company's operations. The works are at Newcastle, New South Wales, and are now in full blast, producing in the half-year ended November 30, 1915. 37,311 tons of open-hearth steel. Additional furnaces arheing erected. Large contracts for rails, billets, etc., have beeu secured for State governments and others. Shell steel for England has been made. Iron ore is shipped from Iron Knob in South Australia to the works, 99,289 tons being despatched during the period. Sales of iron and steel returned £241,403.

The general manager of the company, G. D. Delprat, reported briefly on the mine and works at Broken Hill. There was 114,579 tons of lead-silver-zinc ore extracted. The mill concentrated 98,798 tons, yielding 17,255 tons, averaging 60.61% lead and 28.39 oz. silver per ton. The re-grinding plant treated 82,401 tons of dump tailing for 2372 tons of concentrate with 52.62% lead. The flotation plant treated 141,104 tons of tailing, producing 36,667 tons of concentrate assaying 46.17% zinc, 13.07 oz. silver, and 6.56% lead. The sulphuric-acid plant produced 1969 tons of acid. The rainfall was 4 in. Owing to a labor dispute the whole district was at a standstill early in February of this year.

The net profit for the term was £242,970, from an income of £821,455. Two dividends absorbed £118,101. The surplus is £1,187,678, including £294,116 in cash. Dividends since 1885 total £12,618,302 ($60,500,000).

The Kerr Lake Mining Co., at Cobalt, in its last financial year produced 2,036,963 oz. of silver from 23,035 tons of milling ore and 401 tons of high-grade ore. The cost was 21.45c. per oz. Dividends totaled $620,000.

MINING DECISIONS

Mineral Lease—Effect of Abandonment

A lessee having abandoned a mineral lease, cannot thereafter claim or enforce any right thereunder without first securing the consent of the lessor or a renewal of the lease.

Harris v. Riggs (Indiana), 112 Northeastern, 36. April 6, 1916.

Mill-site Within Forest Reserve

The Act of June 4, 1897, making lands within forest reserves subject to entry under the existing mining laws of the United States confers the right to locate or purchase a mill-site in connection with a lode claim within a National Forest.

James W. Nicol (Land Department), 44 Land Decisions, 197. July 15, 1915.

Vacating Patent—Restoration of Land to Entry

Where as the result of a suit by the United States to vacate and annul a patent issued under coal-land laws, the lands in question are re-conveyed to the United States in accordance with a compromise agreement entered into by the parties to the suit, such lands do not become subject to filing or entry until the re-conveyance thereof has been duly noted upon the records of the local office.

Nathaniel J. Chapin (Land Department), 44 Land Decisions, 222. July 27, 1915.

Placer Location in Alaska—Requisites

The certificate of location of a placer mining claim which has not been verified and which describes the claim as the "No. 1 Bear Creek placer-mining claim," being situated in the White River Mining district, territory of Alaska, and further describes "Bear Creek" as a tributary to "Big Eldorado" vests not title in the owner. The laws of Alaska require the certificate to describe the location of the claim with reference to some "natural object, permanent monument, or well known mining claim" such as will identify the claim in question, and the certificate must be verified before a valid recordation can be made. The location of a mining claim in Alaska under a power of attorney is valid, if the power of attorney is duly recorded at any time before adverse rights accrue, or location is attempted to be made of the same ground by another.

Cloninger v. Finlaison (Alaska), 230 Federal, 98. February 7, 1916.

Mineral Title to Litoral Rights Held Valid

The Alaska Juneau Gold Mining Co. acquired title to certain land on the litoral line of Gastineau channel in the City of Juneau from three sources, namely: by mining lode locations, from purchase of mill-site locations, and by purchase of the possessory rights of certain Indians. The appellant which was a lumber company sought to build wharves over the property in question alleging that the Alaska Juneau company's title was defective because it was claimed under both mineral and non-mineral locations and that the construction of a roadway by the City of Juneau across the property had cut them off from litoral access. Held, that the Alaska Juneau title was good, there being no inconsistency in acquiring titles from all adverse sources. Nor was the mining company's right to the use of the shore extinguished by the construction of a city street without their express consent or grant of right or by exercise of the right of eminent domain.

Werthen Lumber Mills v. Alaska Juneau Gold Mining Co. (Alaska), 229 Federal, 966. March 6, 1916.

BOOK REVIEWS

Rules for Conducting Performance Tests of Power Plant Apparatus. P. 209. Ill., index. The American Society of Mechanical Engineers, New York.

The Committee appointed in April 1909 by the American Society of Mechanical Engineers to revise the testing codes of the Society relative to power-plant apparatus has completed its work. The rules cover tests of boilers, reciprocating steam-engines, steam-turbines, pumping machinery, compressors, blowers, and fans, complete steam-power plants, locomotives, gas-producers, gas and oil-engines, and water-wheels. Needless to state, the Committee has done its work in a thorough and careful manner, and the resulting volume will be indispensable to anyone having to do with power-plant testing.

Copper. From the ore to the metal. By Hugh K. Picard. P. 130. Ill., plan, index. Isaac Pitman & Sons, London and New York. For sale by the Mining and Scientific Press. Price, 85 cents.

This little book is one of a series on common commodities of commerce published by Pitman's. The author is a distinguished metallurgist, well-known in cyanidation and flotation. Several excellent works have been written on the many phases of copper mining and metallurgy, mostly of a technical nature; the volume before us presents the subject in an elementary or popular style, suitable for shareholders interested in copper mines or untechnical readers who desire to get a general idea of the methods of extracting the metal. The latest concentrating tables are described and some space is devoted to flotation processes. Reverberatories receive a short chapter. Costs, marketing, and prices conclude an interesting essay on copper.
